• Task: minimize an objective function (fitness function, loss

 $f: \mathcal{X} \subseteq \mathbb{R}^n \to \mathbb{R}, \qquad \mathbf{x} \mapsto f(\mathbf{x})$

problem domain specific knowledge is used only within the black

Problem Statement

Continuous Domain Search/Optimization

Goal

fast convergence to the global optimum

Problem Statement

 \dots or to a robust solution x \blacktriangleright solution x with small function value f(x) with least search cost there are two conflicting objectives

Typical Examples

- shape optimization (e.g. using CFD)
- model calibration
- parameter calibration

curve fitting, airfoils biological, physical controller, plants, images

Difficulties

- exhaustive search is infeasible
- naive random search takes too long
- deterministic search is not successful / takes too long

Approach: stochastic search, Evolutionary Algorithms

Problem Statement

Problem Statement

Black Box Optimization and Its Difficulties

What Makes a Function Difficult to Solve?

Why stochastic search?

Problem Statement

Continuous Domain Search/Optimization

function) in continuous domain

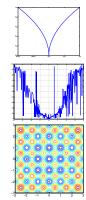

Black Box scenario (direct search scenario)

gradients are not available or not useful

Search costs: number of function evaluations

box, e.g. within an appropriate encoding

- non-linear, non-quadratic, non-convex on linear and quadratic functions much better search policies are available
- ruggedness non-smooth, discontinuous, multimodal, and/or noisy function
- dimensionality (size of search space) (considerably) larger than three
- non-separability dependencies between the objective variables
- ill-conditioning
- non-smooth level sets

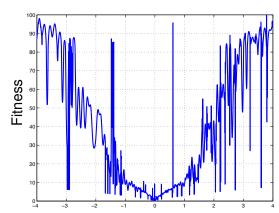

gradient direction Newton direction

Black Box Optimization and Its Difficulties

Black Box Optimization and Its Difficulties

Ruggedness

non-smooth, discontinuous, multimodal, and/or noisy

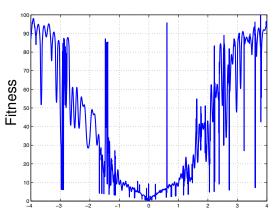

cut from a 5-D example, (easily) solvable with evolution strategies

Problem Statement

Black Box Optimization and Its Difficulties

Ruggedness

non-smooth, discontinuous, multimodal, and/or noisy

cut from a 5-D example, (easily) solvable with evolution strategies

Problem Statement

Non-Separable Problems

Separable Problems

Definition (Separable Problem)

A function f is separable if

$$\arg\min_{(x_1,\ldots,x_n)} f(x_1,\ldots,x_n) = \left(\arg\min_{x_1} f(x_1,\ldots),\ldots,\arg\min_{x_n} f(\ldots,x_n)\right)$$

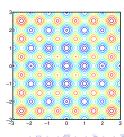

11

 \Rightarrow it follows that f can be optimized in a sequence of n independent 1-D optimization processes

Example: Additively decomposable functions

$$f(x_1,\ldots,x_n) = \sum_{i=1}^n f_i(x_i)$$

Rastrigin function

←□▶←□▶←필▶←필▶ ○ 필 · ♡Q(

Problem Statement

Black Box Optimization and Its Difficulties

Curse of Dimensionality

The term *Curse of dimensionality* (Richard Bellman) refers to problems caused by the rapid increase in volume associated with adding extra dimensions to a (mathematical) space.

Example: Consider placing 20 points equally spaced onto the interval [0,1]. Now consider the 10-dimensional space $[0,1]^{10}$. To get similar coverage in terms of distance between adjacent points requires $20^{10} \approx 10^{13}$ points. 20 points appear now as isolated points in a vast empty space.

Remark: distance measures break down in higher dimensionalities (the central limit theorem kicks in)

Consequence: a search policy that is valuable in small dimensions might be useless in moderate or large dimensional search spaces. Example: exhaustive search.

10

Problem Stateme

Non-Separable Problems

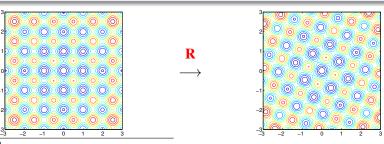

Non-Separable Problems

Building a non-separable problem from a separable one (1,2)

Rotating the coordinate system

- $f: x \mapsto f(x)$ separable
- $f: x \mapsto f(\mathbf{R}x)$ non-separable

R rotation matrix

¹ Hansen, Ostermeier, Gawelczyk (1995). On the adaptation of arbitrary normal mutation distributions in evolution strategies: The generating set adaptation. Sixth ICGA, pp. 57-64, Morgan Kaufmann

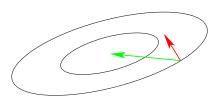

III-Conditioned Problems

Curvature of level sets

Consider the convex-quadratic function

$$f(\mathbf{x}) = \frac{1}{2}(\mathbf{x} - \mathbf{x}^*)^T \mathbf{H}(\mathbf{x} - \mathbf{x}^*) = \frac{1}{2} \sum_i h_{i,i} (x_i - x_i^*)^2 + \frac{1}{2} \sum_{i \neq j} h_{i,j} (x_i - x_i^*) (x_j - x_j^*)$$

$$\mathbf{H} \text{ is Hessian matrix of } f \text{ and symmetric positive definite}$$

gradient direction $-f'(x)^{T}$

Newton direction $-\mathbf{H}^{-1}f'(\mathbf{x})^{\mathrm{T}}$

Ill-conditioning means squeezed level sets (high curvature). Condition number equals nine here. Condition numbers up to 10^{10} are not unusual in real world problems.

If $H \approx I$ (small condition number of H) first order information (e.g. the gradient) is sufficient. Otherwise second order information (estimation of H^{-1}) is necessary.

The CMA-ES

Input: $m \in \mathbb{R}^n$; $\sigma \in \mathbb{R}_+$; $\lambda \in \mathbb{N}_{>2}$, usually $\lambda \geq 5$, default $4 + \lfloor 3 \log n \rfloor$

Set $c_m = 1$; $c_1 \approx 2/n^2$; $c_\mu \approx \mu_w/n^2$; $c_c \approx 4/n$; $c_\sigma \approx 1/\sqrt{n}$; $d_\sigma \approx 1$; $w_{i=1...\lambda}$ decreasing in i and $\sum_i^\mu w_i = 1$, $w_\mu > 0 \ge w_{\mu+1}$, $\mu_w^{-1} := \sum_{i=1}^\mu w_i^2 \approx 3/\lambda$

Initialize ${f C}={f I},$ and $p_{_{f C}}={f 0},$ $p_{_{f \sigma}}={f 0}$

While not terminate

 $m{x}_i = m + \sigma m{y}_i, \quad ext{where } m{y}_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C}) \; ext{for } i = 1, \dots, \lambda \qquad \qquad ext{sampling}$ $m \leftarrow m + c_m \sigma m{y}_w, \quad ext{where } m{y}_w = \sum_{i=1}^{\mu} w_{\mathrm{rk}(i)} \; m{y}_i \qquad \qquad ext{update mean}$

 $\begin{aligned} p_{\sigma} &\leftarrow (1-c_{\sigma}) \, p_{\sigma} + \sqrt{1-(1-c_{\sigma})^2} \sqrt{\mu_w} \, \mathbf{C}^{-\frac{1}{2}} \boldsymbol{y}_w & \text{path for } \sigma \\ p_{c} &\leftarrow (1-c_{c}) \, p_{c} + \mathbf{1}_{[0,2n]} \big\{ \|p_{\sigma}\|^2 \big\} \, \sqrt{1-(1-c_{c})^2} \sqrt{\mu_w} \, \boldsymbol{y}_w & \text{path for } \mathbf{C} \\ \sigma &\leftarrow \sigma \times \exp \left(\frac{c_{\sigma}}{d_{\sigma}} \left(\frac{\|p_{\sigma}\|}{\mathbb{E}\|\mathcal{N}(\mathbf{0},\mathbf{I})\|} - 1 \right) \right) & \text{update of } \sigma \\ \mathbf{C} &\leftarrow \mathbf{C} + c_{\mu} \sum_{i=1}^{\lambda} w_{\mathrm{rk}(i)} \left(\boldsymbol{y}_{i} \boldsymbol{y}_{i}^{\mathsf{T}} - \mathbf{C} \right) + c_{1} (p_{c} \, p_{c}^{\mathsf{T}} - \mathbf{C}) & \text{update } \mathbf{C} \end{aligned}$

Not covered: termination, restarts, useful output, search boundaries and encoding, corrections for: positive definiteness guaranty, $p_{\rm c}$ variance loss, c_{σ} and d_{σ} for large λ

2

Evolution Strategies (ES)

A Search Template

Evolution Strategies

New search points are sampled normally distributed

$$\mathbf{x}_i \sim \mathbf{m} + \sigma \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$
 for $i = 1, \dots, \lambda$

as perturbations of m, where $x_i, m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, $\mathbf{C} \in \mathbb{R}^{n \times n}$

where

- the mean vector $m \in \mathbb{R}^n$ represents the favorite solution
- the so-called step-size $\sigma \in \mathbb{R}_+$ controls the *step length*
- the covariance matrix $C \in \mathbb{R}^{n \times n}$ determines the shape of the distribution ellipsoid

here, all new points are sampled with the same parameters

The question remains how to update m, \mathbb{C} , and σ

Stochastic Search

A black box search template to minimize $f: \mathbb{R}^n \to \mathbb{R}$

Initialize distribution parameters θ , set population size $\lambda \in \mathbb{N}$ While not terminate

- **1** Sample distribution $P(x|\theta) \rightarrow x_1, \dots, x_{\lambda} \in \mathbb{R}^n$
- 2 Evaluate x_1, \ldots, x_{λ} on f
- **3** Update parameters $\theta \leftarrow F_{\theta}(\theta, x_1, \dots, x_{\lambda}, f(x_1), \dots, f(x_{\lambda}))$

Everything depends on the definition of P and F_{ℓ}

deterministic algorithms are covered as well

In many Evolutionary Algorithms the distribution P is implicitly defined via operators on a population, in particular, selection, recombination and mutation

Natural template for (incremental) Estimation of Distribution Algorithms ~

Evolution Strategies (ES)

The Normal Distribution

Why Normal Distributions?

- widely observed in nature, for example as phenotypic traits
- only stable distribution with finite variance

stable means that the sum of normal variates is again normal:

$$\mathcal{N}(x, \mathbf{A}) + \mathcal{N}(y, \mathbf{B}) \sim \mathcal{N}(x + y, \mathbf{A} + \mathbf{B})$$

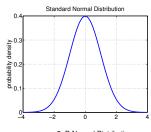

helpful in design and analysis of algorithms related to the *central limit theorem*

o most convenient way to generate isotropic search points

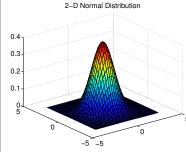

the isotropic distribution does not favor any direction, rotational invariant

maximum entropy distribution with finite variance the least possible assumptions on f in the distribution shape

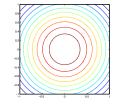

Normal Distribution

probability density of the 1-D standard normal distribution

probability density of a 2-D normal distribution

29

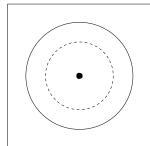

4 D > 4 P > 4 B > 4 B > B 9 9 P

Evolution Strategies (ES)

The Normal Distribution

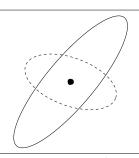

... any covariance matrix can be uniquely identified with the iso-density ellipsoid $\{x \in \mathbb{R}^n \mid (x-m)^{\mathrm{T}} \mathbf{C}^{-1} (x-m) = n\}$

 $\mathcal{N}(\mathbf{m}, \sigma^2 \mathbf{I}) \sim \mathbf{m} + \sigma \mathcal{N}(\mathbf{0}, \mathbf{I})$ one degree of freedom σ components are

independent standard normally distributed

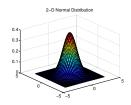

where I is the identity matrix (isotropic case) and D is a diagonal matrix (reasonable for separable problems) and $\mathbf{A} \times \mathcal{N}(\mathbf{0}, \mathbf{I}) \sim \mathcal{N}(\mathbf{0}, \mathbf{A}\mathbf{A}^{\mathrm{T}})$ holds for all \mathbf{A} .

The Multi-Variate (*n*-Dimensional) Normal Distribution

Any multi-variate normal distribution $\mathcal{N}(m,\mathbb{C})$ is uniquely determined by its mean value $m \in \mathbb{R}^n$ and its symmetric positive definite $n \times n$ covariance matrix \mathbb{C} .

The mean value m

- determines the displacement (translation)
- value with the largest density (modal value)
- the distribution is symmetric about the distribution mean

Evolution Strategies (ES) The Normal Distribution

Multivariate Normal Distribution and Eigenvalues

For any positive definite symmetric C,

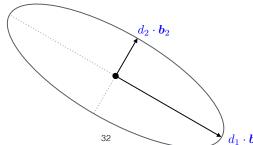

$$\mathbf{C} = d_1^2 \boldsymbol{b}_1 \boldsymbol{b}_1^{\mathrm{T}} + \dots + d_N^2 \boldsymbol{b}_N \boldsymbol{b}_N^{\mathrm{T}}$$

 d_i : square root of the eigenvalue of C

 b_i : eigenvector of C, corresponding to d_i

The multivariate normal distribution $\mathcal{N}(m, \mathbf{C})$

 $\mathcal{N}(\boldsymbol{m}, \mathbf{C}) \sim \boldsymbol{m} + \mathcal{N}(0, d_1^2)\boldsymbol{b}_1 + \cdots + \mathcal{N}(0, d_N^2)\boldsymbol{b}_N$

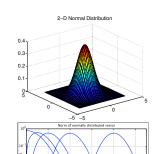

Evolution Strategies (ES)

The Normal Distribution

Effect of Dimensionality

vet: maximum entropy distribution

also consider a difference between two vectors:

$$\|\mathcal{N}(\mathbf{0},\mathbf{I}) - \mathcal{N}(\mathbf{0},\mathbf{I})\| \sim \|\mathcal{N}(\mathbf{0},\mathbf{I}) + \mathcal{N}(\mathbf{0},\mathbf{I})\| \sim \sqrt{2} \|\mathcal{N}(\mathbf{0},\mathbf{I})\|$$

Evolution Strategies (ES) The Normal Distribution

The $(\mu/\mu, \lambda)$ -ES, Update of the Distribution Mean

Non-elitist selection and intermediate (weighted) recombination

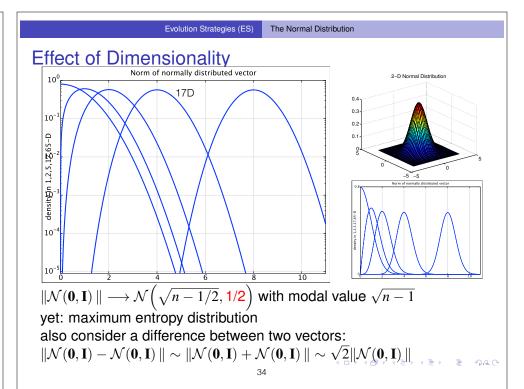

Given the *i*-th solution point
$$x_i = m + \sigma \underbrace{\mathcal{N}_i(\mathbf{0}, \mathbf{C})}_{=:\mathbf{v}} = m + \sigma y_i$$

Let $x_{i:\lambda}$ the *i*-th ranked solution point, such that $f(x_{1:\lambda}) \leq \cdots \leq f(x_{\lambda:\lambda})$.

$$m \leftarrow \sum_{i=1}^{\mu} w_i x_{i:\lambda} = m + \sigma \sum_{j=1}^{\mu} w_i y_{i:\lambda}$$

$$w_1 \ge \dots \ge w_{\mu} > 0$$
, $\sum_{i=1}^{\mu} w_i = 1$, $\frac{1}{\sum_{i=1}^{\mu} w_i^2} =: \mu_w \approx \frac{\lambda}{4}$

The best μ points are selected from the new solutions (non-elitistic) and weighted intermediate recombination is applied.

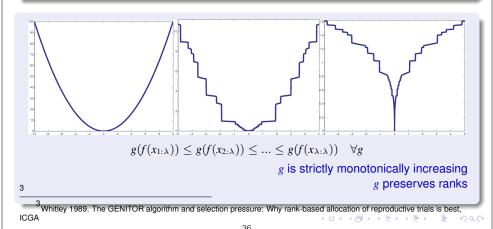

Evolution Strategies (ES) Invariance

Invariance Under Monotonically Increasing Functions

Rank-based algorithms

Update of all parameters uses only the ranks

$$f(x_{1:\lambda}) \le f(x_{2:\lambda}) \le \dots \le f(x_{\lambda:\lambda})$$

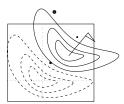

Basic Invariance in Search Space

translation invariance

is true for most optimization algorithms

$$f(\mathbf{x}) \leftrightarrow f(\mathbf{x} - \mathbf{a})$$

Identical behavior on f and f_a

$$f: \mathbf{x} \mapsto f(\mathbf{x}), \quad \mathbf{x}^{(t=0)} = \mathbf{x}_0$$

 $f_{\mathbf{a}}: \mathbf{x} \mapsto f(\mathbf{x} - \mathbf{a}), \quad \mathbf{x}^{(t=0)} = \mathbf{x}_0 + \mathbf{a}$

37

No difference can be observed w.r.t. the argument of *f*

Step-Size Control

Evolution Strategies

Recalling

New search points are sampled normally distributed

$$\mathbf{x}_i \sim \mathbf{m} + \sigma \, \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$
 for $i = 1, \dots, \lambda$

as perturbations of m, where $x_i, m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, $\mathbb{C} \in \mathbb{R}^{n \times n}$

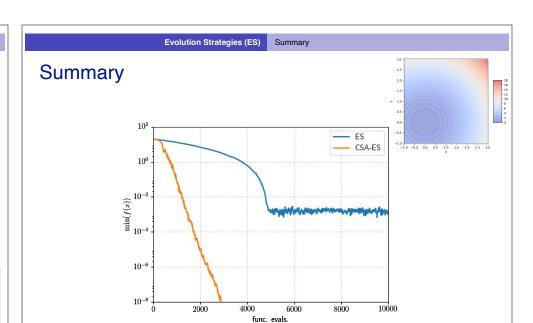

where

- the mean vector $m \in \mathbb{R}^n$ represents the favorite solution and $m \leftarrow \sum_{i=1}^{\mu} w_i x_{i:\lambda}$
- the so-called step-size $\sigma \in \mathbb{R}_+$ controls the step length
- the covariance matrix $\mathbb{C} \in \mathbb{R}^{n \times n}$ determines the shape of the distribution ellipsoid

The remaining question is how to update σ and \mathbb{C} .

On 20D Sphere Function: $f(\mathbf{x}) = \sum_{i=1}^{N} [\mathbf{x}]_{i}^{2}$

ES without adaptation can't approach the optimum ⇒ adaptation required

Step-Size Control

Why Step-Size Control

Methods for Step-Size Control

• 1/5-th success rule ab, often applied with "+"-selection

increase step-size if more than 20% of the new solutions are successful, decrease otherwise

• σ -self-adaptation^c, applied with ","-selection

mutation is applied to the step-size and the better, according to the objective function value, is selected

simplified "global" self-adaptation

• path length control^d (Cumulative Step-size Adaptation, CSA)^e

self-adaptation derandomized and non-localized

^aRechenberg 1973, *Evolutionsstrategie, Optimierung technischer Systeme nach Prinzipien der biologischen* Evolution, Frommann-Holzboog

^bSchumer and Steiglitz 1968. Adaptive step size random search. *IEEE TAC*

^CSchwefel 1981, Numerical Optimization of Computer Models, Wiley

^dHansen & Ostermeier 2001, Completely Derandomized Self-Adaptation in Evolution Strategies, *Evol. Comput.* 9(2)

^eOstermeier *et al* 1994, Step-size adaptation based on non-local use of selection information, *PPSN IV*

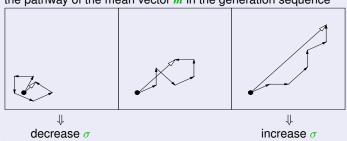

Path Length Control (CSA)

The Concept of Cumulative Step-Size Adaptation

$$\begin{array}{rcl} \boldsymbol{x}_i & = & \boldsymbol{m} + \sigma \, \boldsymbol{y}_i \\ \boldsymbol{m} & \leftarrow & \boldsymbol{m} + \sigma \, \boldsymbol{y}_w \end{array}$$

Measure the length of the evolution path

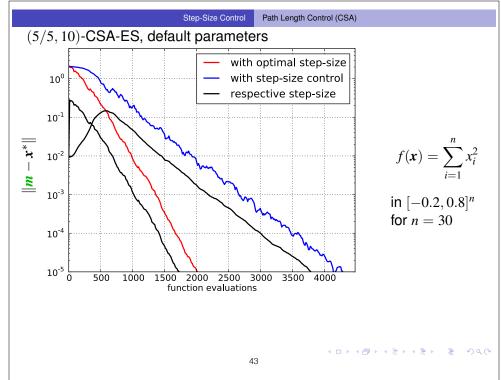

the pathway of the mean vector m in the generation sequence

loosely speaking steps are

- perpendicular under random selection (in expectation)
- perpendicular in the desired situation (to be most efficient)

. |団▶∢≣▶∢≣▶ ≣ りqで

Path Length Control (CSA)

The Equations

Initialize $m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, evolution path $p_{\sigma} = 0$, set $c_{\sigma} \approx 4/n$, $d_{\sigma} \approx 1$.

Step-Size Control

4 D > 4 D > 4 E > 4 E > E 900

Step-Size Control Alternatives to CSA

Two-Point Step-Size Adaptation (TPA)

• Sample a pair of symmetric points along the previous mean shift

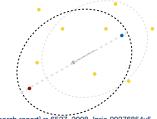

$$x_{1/2} = m^{(g)} \pm \sigma^{(g)} \frac{\|\mathcal{N}(\mathbf{0}, \mathbf{I})\|}{\|m^{(g)} - m^{(g-1)}\|_{\mathbf{C}^{(g)}}} (m^{(g)} - m^{(g-1)}) \qquad \|x\|_{\mathbf{C}} := x^{\mathsf{T}} \mathbf{C}^{-1} x$$

• Compare the ranking of x_1 and x_2 among λ current populations

$$s^{(g+1)} = (1 - c_s)s^{(g)} + c_s \frac{\text{rank}(x_2) - \text{rank}(x_1)}{\lambda - 1}$$

Update the step-size

$$\sigma^{(g+1)} = \sigma^{(g)} \exp\left(\frac{s^{(g+1)}}{d_{\sigma}}\right)$$

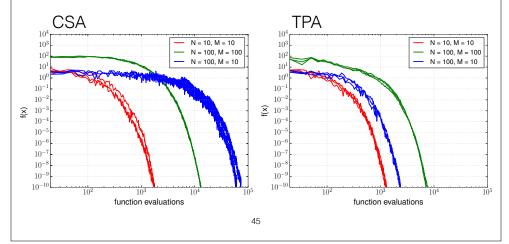

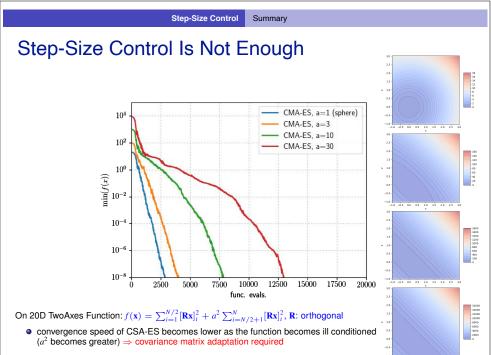

[Hansen, 2008] Hansen, N. (2008). CMA-ES with two-point step-size adaptation. [research report] rr-6527, 2008. Inria-00276854v5. [Hainsen, 2004] Hainsen, N., Atamna, A., and Auger, A. (2014). How to assess step-size adaptation mechanisms in randomised search. In Parallel Problem Solving from Nature–PPSN XIII, pages 60–69. Springer.

On Sphere with Low Effective Dimension

On a function with low effective dimension

- $f(x) = \sum_{i=1}^{M} [x]_i^2, \quad x \in \mathbb{R}^N, \quad M \leq N.$
- N-M variables do not affect the function value

Alternatives: Success-Based Step-Size Control

comparing the fitness distributions of current and previous iterations

Generalizations of 1/5th-success-rule for non-elitist and multi-recombinant ES

- Median Success Rule [Ait Elhara et al., 2013]
- Population Success Rule [Loshchilov, 2014]

controls a success probability

An advantage over CSA and TPA: Cheap Computation

- It depends only on λ .
- cf. CSA and TPA require a computation of $C^{-1/2}x$ and $C^{-1}x$,

Covariance Matrix Adaptation (CMA)

Evolution Strategies

Recalling

New search points are sampled normally distributed

$$\mathbf{x}_i \sim \mathbf{m} + \sigma \, \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$
 for $i = 1, \dots, \lambda$

as perturbations of m, where $x_i, m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, $\mathbf{C} \in \mathbb{R}^{n \times n}$

where

- the mean vector $m \in \mathbb{R}^n$ represents the favorite solution
- the so-called step-size $\sigma \in \mathbb{R}_+$ controls the step length
- the covariance matrix $C \in \mathbb{R}^{n \times n}$ determines the shape of the distribution ellipsoid

The remaining question is how to update C.

Covariance Matrix Adaptation (CMA)

Cumulation—the Evolution Path

Cumulation

The Evolution Path

Evolution Path

Conceptually, the evolution path is the search path the strategy takes over a number of generation steps. It can be expressed as a sum of consecutive steps of the mean m.

An exponentially weighted sum of steps \mathbf{v}_w is used

$$p_{
m c} \propto \sum_{i=0}^{g} \ \underbrace{(1-c_{
m c})^{g-i}}_{ ext{exponentially}} \ y_{w}^{(i)}$$

The recursive construction of the evolution path (cumulation):

$$p_{\mathrm{c}} \leftarrow \underbrace{(1-c_{\mathrm{c}})}_{\mathrm{decay factor}} p_{\mathrm{c}} + \underbrace{\sqrt{1-(1-c_{\mathrm{c}})^2} \sqrt{\mu_{w}}}_{\mathrm{normalization factor}} \underbrace{y_{w}}_{\mathrm{input} = \frac{m-m_{\mathrm{old}}}{c}}$$

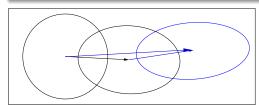

where $\mu_w=rac{1}{\sum w_i^2}$, $c_{\mathbf{c}}\ll 1$. History information is accumulated in the evolution path.

Cumulation

The Evolution Path

Evolution Path

Conceptually, the evolution path is the search path the strategy takes over a number of generation steps. It can be expressed as a sum of consecutive steps of the mean m.

An exponentially weighted sum of steps \mathbf{v}_{w} is used

$$p_{
m c} \propto \sum_{i=0}^{g} \underbrace{(1-c_{
m c})^{g-i}}_{ ext{exponentially}} y_{\scriptscriptstyle w}^{(i)}$$

Covariance Matrix Adaptation (CMA)

$$p_{\rm c} \leftarrow \underbrace{(1-c_{\rm c})}_{
m decay \, factor} p_{\rm c} + \underbrace{\sqrt{1-(1-c_{\rm c})^2} \sqrt{\mu_{\rm w}}}_{
m normalization \, factor} y_{\rm w} \underbrace{y_{\rm w}}_{
m input} = \underbrace{{}^{m-m}_{\rm old}}_{
m mod}$$

where $\mu_w=rac{1}{\sum w_i^2},\,c_{
m c}\ll 1.$ History information is accumulated in the evolution path.

Covariance Matrix Adaptation (CMA)

Cumulation—the Evolution Path

"Cumulation" is a widely used technique and also know as

- exponential smoothing in time series, forecasting
- exponentially weighted mooving average
- *iterate averaging* in stochastic approximation
- momentum in the back-propagation algorithm for ANNs

"Cumulation" conducts a *low-pass* filtering, but there is more to it...

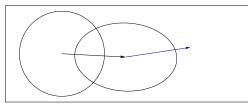

...why?

4□ > 4□ > 4 = > 4 = > = 900

Cumulation

$$\mathbf{C} \leftarrow (1 - c_{\text{cov}})\mathbf{C} + c_{\text{cov}}\mu_{w}\mathbf{y}_{w}\mathbf{y}_{w}^{\mathrm{T}}$$

Utilizing the Evolution Path We used $y_w y_w^{\rm T}$ for updating C. Because $y_w y_w^{\rm T} = -y_w (-y_w)^{\rm T}$ the sign of y_w is lost.

where $\mu_w = \frac{1}{\sum w_i^2}$, $c_{\rm cov} \ll c_{\rm c} \ll 1$ such that $1/c_{\rm c}$ is the "backward time horizon".

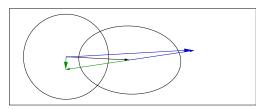

Covariance Matrix Adaptation (CMA) Cumulation—the Evolution Path

Cumulation

 $\mathbf{C} \leftarrow (1 - c_{\text{cov}})\mathbf{C} + c_{\text{cov}}\mu_w \mathbf{y}_w \mathbf{y}_w^{\text{T}}$

Utilizing the Evolution Path We used $y_w y_w^{\mathrm{T}} = -y_w (-y_w)^{\mathrm{T}}$ the sign of y_w is lost.

The sign information (signifying correlation between steps) is (re-)introduced by using the evolution path.

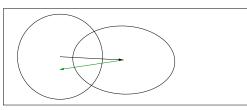

$$p_{c} \leftarrow \underbrace{(1-c_{c})}_{\text{decay factor}} p_{c} + \underbrace{\sqrt{1-(1-c_{c})^{2}}\sqrt{\mu_{w}}}_{\text{normalization factor}} y_{w}$$
 $C \leftarrow (1-c_{cov})C + c_{cov} \underbrace{p_{c}p_{c}}_{\text{poly}}^{T}$

where $\mu_w = \frac{1}{\sum w_i^2}$, $c_{cov} \ll c_c \ll 1$ such that $1/c_c$ is the "backward time horizon".

Cumulation

 $\mathbf{C} \leftarrow (1 - c_{\text{cov}})\mathbf{C} + c_{\text{cov}}\mu_w \mathbf{y}_w \mathbf{y}_w^{\text{T}}$

Utilizing the Evolution Path We used $y_w y_w^T$ for updating \mathbb{C} . Because $y_w y_w^T = -y_w (-y_w)^T$ the sign of y_w is lost.

$$p_{\rm c} \leftarrow \underbrace{(1-c_{\rm c})}_{
m decay factor} p_{\rm c} + \underbrace{\sqrt{1-(1-c_{\rm c})^2}\sqrt{\mu_{\scriptscriptstyle W}}}_{
m normalization factor} y_{\scriptscriptstyle W}$$
 $C \leftarrow (1-c_{\rm cov}){\rm C} + c_{\rm cov}\underbrace{p_{\rm c}p_{\rm c}^{\ \ T}}_{
m rank-one}$

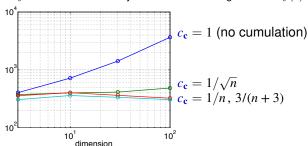

where $\mu_w=\frac{1}{\sum w_i^2},\,c_{\rm cov}\ll c_{\rm c}\ll 1$ such that $1/c_{\rm c}$ is the "backward time horizon".

Covariance Matrix Adaptation (CMA) Cumulation—the Evolution Path

Using an evolution path for the rank-one update of the covariance matrix reduces the number of function evaluations to adapt to a straight ridge from about $\mathcal{O}(n^2)$ to $\mathcal{O}(n)$. (a)

^aHansen & Auger 2013. Principled design of continuous stochastic search: From theory to practice.

Number of *f*-evaluations divided by dimension on the cigar function $f(x) = x_1^2 + 10^6 \sum_{i=2}^n x_i^2$

The overall model complexity is n^2 but important parts of the model can be learned in time of order n

Rank-µ Update

$$\mathbf{x}_{i} = \mathbf{m} + \sigma \mathbf{y}_{i}, \quad \mathbf{y}_{i} \sim \mathcal{N}_{i}(\mathbf{0}, \mathbf{C}), \\
\mathbf{m} \leftarrow \mathbf{m} + \sigma \mathbf{y}_{w} \quad \mathbf{y}_{w} = \sum_{i=1}^{\mu} \mathbf{w}_{i} \mathbf{y}_{i:\lambda}$$

The rank- μ update extends the update rule for large population sizes λ using $\mu > 1$ vectors to update \mathbb{C} at each generation step.

$$\mathbf{C}_{\mu} = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda} \mathbf{y}_{i:\lambda}^{\mathrm{T}}$$

$$\mathbf{C} \leftarrow (1 - c_{\text{cov}}) \mathbf{C} + c_{\text{cov}} \mathbf{C}_{\mu}$$

Summary

Active Covariance Matrix Adaptation + Cumulation

$$\boldsymbol{C} \leftarrow (1 - c_1 - c_{\mu} + \boldsymbol{c}_{\mu}^{-}) \boldsymbol{C} + c_1 \boldsymbol{p}_c \boldsymbol{p}_c^T + c_{\mu} \sum_{i=1}^{\lfloor \lambda/2 \rfloor} w_i \boldsymbol{y}_{i:\lambda} \boldsymbol{y}_{i:\lambda}^T - \boldsymbol{c}_{\mu}^{-} \sum_{i=\lambda-\lfloor \lambda/2 \rfloor+1}^{\lambda} |w_i| \boldsymbol{y}_{i:\lambda} \boldsymbol{y}_{i:\lambda}^T$$

- $-|w_i| < 0$ (for $i \ge \lambda \lfloor \lambda/2 \rfloor + 1$): negative weight assigned to $y_{i:\lambda}$, $\sum_{i=\lambda-\mu}^{\lambda} |w_i| = 1$.
- $c_{\mu}^{-} > 0$: learning rate for the active update

CMA-ES Summary

Input: $m \in \mathbb{R}^n$; $\sigma \in \mathbb{R}_+$; $\lambda \in \mathbb{N}_{\geq 2}$, usually $\lambda \geq 5$, default $4 + \lfloor 3 \log n \rfloor$

Set $c_m = 1$; $c_1 \approx 2/n^2$; $c_u \approx \mu_w/n^2$; $c_c \approx 4/n$; $c_\sigma \approx 1/\sqrt{n}$; $d_\sigma \approx 1$; $w_{i=1...\lambda}$ decreasing in i and $\sum_{i=1}^{\mu} w_{i} = 1, w_{\mu} > 0 \ge w_{\mu+1}, \mu_{w}^{-1} := \sum_{i=1}^{\mu} w_{i}^{2} \approx 3/\lambda$

Initialize C = I, and $p_c = 0$, $p_{\sigma} = 0$

While not terminate

$$\begin{split} & x_i = m + \sigma \boldsymbol{y}_i, \quad \text{where } \boldsymbol{y}_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C}) \text{ for } i = 1, \dots, \lambda \qquad \text{sampling} \\ & m \leftarrow m + c_m \sigma \boldsymbol{y}_w, \quad \text{where } \boldsymbol{y}_w = \sum_{i=1}^{\mu} w_{\mathrm{rk}(i)} \, \boldsymbol{y}_i \qquad \text{update mean} \\ & p_\sigma \leftarrow (1 - c_\sigma) \, p_\sigma + \sqrt{1 - (1 - c_\sigma)^2} \sqrt{\mu_w} \, \mathbf{C}^{-\frac{1}{2}} \, \boldsymbol{y}_w \qquad \text{path for } \sigma \\ & p_\mathrm{c} \leftarrow (1 - c_\mathrm{c}) \, p_\mathrm{c} + \mathbf{1}_{[0,2n]} \! \left\{ \lVert p_\sigma \rVert^2 \right\} \sqrt{1 - (1 - c_\mathrm{c})^2} \sqrt{\mu_w} \, \boldsymbol{y}_w \quad \text{path for } \mathbf{C} \\ & \sigma \leftarrow \sigma \times \exp \left(\frac{c_\sigma}{d_\sigma} \left(\frac{\lVert p_\sigma \rVert}{\mathsf{E} \lVert \mathcal{N}(\mathbf{0}, \mathbf{I}) \rVert} - 1 \right) \right) \qquad \text{update of } \sigma \\ & \mathbf{C} \leftarrow \mathbf{C} + c_\mu \sum_{i=1}^{\lambda} w_{\mathrm{rk}(i)} \left(\boldsymbol{y}_i \boldsymbol{y}_i^\mathsf{T} - \mathbf{C} \right) + c_1 (p_\mathrm{c} \, p_\mathrm{c}^\mathsf{T} - \mathbf{C}) \qquad \text{update } \mathbf{C} \end{split}$$

Not covered: termination, restarts, useful output, search boundaries and encoding, corrections for: positive definiteness guaranty, p_c variance loss, c_{σ} and d_{σ} for large λ

What can/should the users do? Strategy Parameters and Initialization

Default Parameter Values

CMA-ES + (B)IPOP Restart Strategy = Quasi-Parameter Free Optimizer

The following parameters were identified in carefully chosen experimental set ups.

- related to selection and recombination
 - λ : offspring number, new solutions sampled, population size
 - μ: parent number, solutions involved in mean update
 - w_i: recombination weights
- related to C-update
 - $1-c_c$: decay rate for the evolution path, cumulation factor
 - c₁: learning rate for rank-one update of C
 - c_{μ} : learning rate for rank- μ update of C
- related to σ -update
 - $1 c_{\sigma}$: decay rate of the evolution path
 - d_{σ} : damping for σ -change

The default values depends only on the dimension. They do in the first place not depend on the objective function.

Topics

- 3. What can/should the users do for the CMA-ES to work effectively on their problem?
 - Choice of problem formulation and encoding (not covered)
 - Choice of initial solution and initial step-size
 - Restarts, Increasing Population Size
 - Restricted Covariance Matrix

What can/should the users do? Strategy Parameters and Initialization

Parameters to be set depending on the problem

Initialization and termination conditions

The following should be set or implemented depending on the problem.

- related to the initial search distribution
 - $m^{(0)}$: initial mean vector
 - $\sigma^{(0)}$ (or $\sqrt{C_{i,i}^{(0)}}$): initial (coordinate-wise) standard deviation
- related to stopping conditions
 - max. func. evals.
 - max. iterations
 - function value tolerance
 - min. axis length
 - stagnation

Practical Hints:

- start with an initial guess $m^{(0)}$ with a relatively small step-size $\sigma^{(0)}$ to *locally* improve the current quess:
- then increase the step-size, e.g., by factor of 10, to globally search for a better solution.

Python CMA-ES Implementation

https://github.com/CMA-ES/pycma

pycma

A Python implementation of CMA-ES and a few related numerical optimization tools.

The Covariance Matrix Adaptation Evolution Strategy (CMA-ES) is a stochastic derivative-free numerical optimization algorithm for difficult (non-convex, ill-conditioned, multi-modal, rugged, noisy) optimization problems in continuous search spaces.

Useful links:

- · A quick start guide with a few usage examples
- · The API Documentation
- · Hints for how to use this (kind of) optimization module in practice

Installation of the latest release

Type

python -m pip install cma

in a system shell to install the latest release from the Python Package Index (PyPI). The release link also provides more installation hints and a quick start guide.

What can/should the users do?

Multimodality

Multimodality

Two approaches for multimodal functions: Try again with

- a larger population size
- a smaller initial step-size (and random initial mean vector)

Multimodality

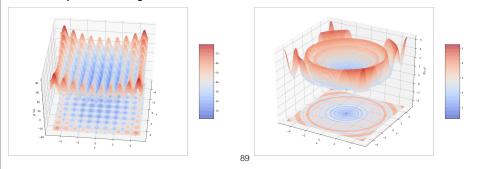

Multimodality

Approaches for multimodal functions: Try again with

- the final solution as initial solution (non-elitist) and small step-size
- a larger population size
- a different initial mean vector (and a smaller initial step-size)

A restart with a **large population size** helps if the objective function has a well global structure

- functions such as Schaffer, Rastrigin, BBOB function 15~19
- loosely, unimodal global structure + deterministic noise

What can/should the users do?

Multimodality

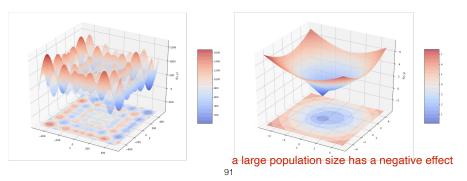

Multimodality

Approaches for multimodal functions: Try again with

- the final solution as initial solution (non-elitist) and small step-size
- a larger population size
- a different initial mean vector (and a smaller initial step-size)

A restart with a **small initial step-size** helps if the objective function has a **weak global structure**

• functions such as Schwefel, Bi-Sphere, BBOB function 20~24

What can/should the users do?

Multimodality

Multimodality

Hansen and Kern. Evaluating the CMA Evolution Strategy on Multimodal Test Functions, PPSN 2004.

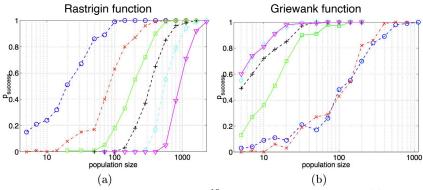

Fig. 1. Success rate to reach $f_{\text{stop}} = 10^{-10}$ versus population size for (a) Rastrigin function (b) Griewank function for dimensions n = 2 (' $--\bigcirc$ -'), n = 5 (' $--\times$ -'), n = 10 (' $--\bigcirc$ -'), n = 20 ('--+--'), n = 40 (' $--\bigcirc$ -'), and n = 80 (' $--\bigcirc$ -').

What can/should the users do?

Restart Strategy

Restart Strategy

It makes the CMA-ES parameter free

IPOP: Restart with increasing the population size

- start with the default population size
- double the population size after each trial (parameter sweep)
- may be considered as gold standard for automated restarts

BIPOP: IPOP regime + Local search regime

- IPOP regime: restart with increasing population size
- Local search regime: restart with a smaller step-size and a smaller population size than the IPOP regime

Topics

- 3. What can/should the users do for the CMA-FS to work effectively on their problem?
 - Choice of problem formulation and encoding (not covered)
 - Choice of initial solution and initial step-size
 - Restarts, Increasing Population Size
 - Restricted Covariance Matrix

What can/should the users do? Restricted Covariance Matrix

Variants with Restricted Covariance Matrix

CMA-ES Variants with Restricted Covariance Matrices

- Sep-CMA [Ros and Hansen, 2008]
 - $ightharpoonup C = \mathbf{D}$. **D**: Diagonal
- VD-CMA [Akimoto et al., 2014]
 - $C = \mathbf{D}(\mathbf{I} + vv^{\mathrm{T}})\mathbf{D}$. D: Diagonal, $v \in \mathbb{R}^{N}$.
- LM-CMA [Loshchilov, 2014]
 - $C = \mathbf{I} + \sum_{i=1}^k \mathbf{v}_i \mathbf{v}_i^{\mathrm{T}}. \ \mathbf{v}_i \in \mathbb{R}^N.$
- VkD-CMA [Akimoto and Hansen, 2016]
 - $ightharpoonup C = \mathbf{D}(\mathbf{I} + \sum_{i=1}^k \mathbf{v}_i \mathbf{v}_i^{\mathrm{T}}) \mathbf{D}. \ \mathbf{v}_i \in \mathbb{R}^N.$

What can/should the users do?

Restricted Covariance Matrix

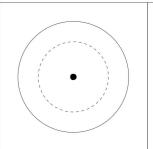

Motivation of the Restricted Covariance Matrix

Bottlenecks of the CMA-ES on high dimensional problems

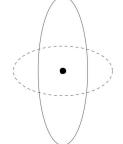

- \bigcirc $\mathcal{O}(N^2)$ Time and Space Complexities
 - ▶ to store and update $C \in \mathbb{R}^{N \times N}$
 - ▶ to compute the eigen decomposition of *C*

What can/should the users do? Restricted Covariance Matrix

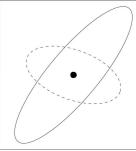

Separable CMA (Sep-CMA)

 $\mathcal{N}(\mathbf{m}, \sigma^2 \mathbf{I}) \sim \mathbf{m} + \sigma \mathcal{N}(\mathbf{0}, \mathbf{I})$ one degree of freedom σ

 $\mathcal{N}(m, \mathbf{D}^2) \sim m + \mathbf{D} \mathcal{N}(\mathbf{0}, \mathbf{I})$

 $\mathcal{N}(m, \mathbf{C}) \sim m + \mathbf{C}^{\frac{1}{2}} \mathcal{N}(\mathbf{0}, \mathbf{I})$ *n* degrees of freedom $(n^2 + n)/2$ degrees of freedom

CMA
$$C_{\text{cma}}^{(t+1)} = C^{(t)} + c_1 \left(p_c p_c^{\text{T}} - C^{(t)} \right) + c_{\mu} \sum_{i=1}^{\mu} w_i \left((x_i - m^{(t)})(x_i - m^{(t)})^{\text{T}} - C^{(t)} \right)$$

SEP
$$[C_{\text{sep}}^{(t+1)}]_{k,k} = [C^{(t)}]_{k,k} + \frac{c_1}{c_1} \left([p_e]_k^2 - [C^{(t)}]_{k,k} \right) + \frac{c_\mu}{c_1} \sum_{i=1}^{\mu} w_i \left([\mathbf{x}_i - \mathbf{m}^{(t)}]_k^2 - [C^{(t)}]_{k,k} \right)$$

$$(\mathbf{N} + \mathbf{2})/3 \text{ times greater than CMA}$$

Demo: On 100D Separable Ellipsoid Function

- CMA needed 10 times more FEs + more CPU time
- However, Sep-CMA won't be able to solve rotated ellipsoid function as efficiently as it solves separable ellipsoid

97

Summary and Final Remarks

Main Characteristics of (CMA) Evolution Strategies

- Multivariate normal distribution to generate new search points follows the maximum entropy principle
- 2 Rank-based selection implies invariance, same performance on g(f(x)) for any increasing g more invariance properties are featured
- Step-size control facilitates fast (log-linear) convergence and possibly linear scaling with the dimension in CMA-ES based on an evolution path (a non-local trajectory)
- Covariance matrix adaptation (CMA) increases the likelihood of previously successful steps and can improve performance by orders of magnitude

the update follows the natural gradient $\mathbb{C} \propto H^{-1} \iff$ adapts a variable metric \iff new (rotated) problem representation $\implies f: x \mapsto g(x^T H x)$ reduces to $x \mapsto x^T x$

Summary and Final Remarks

Summary and Final Remarks

98

Summary and Final Remarks

Limitations

of CMA Evolution Strategies

- internal CPU-time: $10^{-8}n^2$ seconds per function evaluation on a 2GHz PC, tweaks are available
 - 1 000 000 *f*-evaluations in 100-D take 100 seconds *internal* CPU-time variants with restricted covariance matrix such as Sep-CMA
- better methods are presumably available in case of
 - partly separable problems
 - specific problems, for example with cheap gradients specific methods
 - ▶ small dimension ($n \ll 10$)

for example Nelder-Mead

ightharpoonup small running times (number of f-evaluations < 100n) model-based methods

Thank you

Theoretical Foundations

CMA-ES = Natural Evolution Strategy + Cumulation

Natural gradient descend using the MC approximation and the normal distribution

Rewriting the update of the distribution mean

$$m_{\mathsf{new}} \leftarrow \sum_{i=1}^{\mu} w_i x_{i:\lambda} = m + \sum_{i=1}^{\mu} w_i (x_{i:\lambda} - m)$$

natural gradient for mean $\frac{\tilde{\partial}}{\tilde{z}} \hat{E}(w \circ P_f(f(x)) | m, C)$

Rewriting the update of the covariance matrix¹³

$$\begin{split} \mathbf{C}_{\mathsf{new}} \leftarrow \mathbf{C} + c_1 & (p_{\mathbf{c}} p_{\mathbf{c}}^{\mathsf{T}} - \mathbf{C}) \\ & + \frac{c_{\mu}}{\sigma^2} \sum_{i=1}^{\mu} w_i \bigg(\underbrace{(\pmb{x}_{i:\lambda} - \pmb{m}) \, (\pmb{x}_{i:\lambda} - \pmb{m})^{\mathsf{T}}}_{\text{rank-}\mu} - \sigma^2 \mathbf{C} \bigg) \\ & \text{natural gradient for covariance matrix } \frac{\tilde{\partial}}{\tilde{\partial} \mathbf{C}} \hat{\mathbf{E}} (w \circ P_f(f(\pmb{x})) | \pmb{m}, \mathbf{C}) \end{split}$$

Theoretical Foundations

Natural Gradient Descend

• Consider $\arg\min_{\alpha} \mathrm{E}(f(x)|\theta)$ under the sampling distribution $x \sim p(.|\theta)$ we could improve $E(f(x)|\theta)$ by following the gradient $\nabla_{\theta}E(f(x)|\theta)$:

$$\theta \leftarrow \theta - \eta \nabla_{\theta} \mathbf{E}(f(\mathbf{x})|\theta), \qquad \eta > 0$$

 ∇_{θ} depends on the parameterization of the distribution, therefore

Consider the natural gradient of the expected transformed fitness

$$\widetilde{\nabla}_{\theta} \operatorname{E}(w \circ P_f(f(\mathbf{x}))|\theta) = F_{\theta}^{-1} \nabla_{\theta} \operatorname{E}(w \circ P_f(f(\mathbf{x}))|\theta)$$
$$= \operatorname{E}(w \circ P_f(f(\mathbf{x}))F_{\theta}^{-1} \nabla_{\theta} \ln p(\mathbf{x}|\theta))$$

using the Fisher information matrix $F_{\theta} = \left(\left(\mathbb{E}^{\frac{\partial^2 \log p(x|\theta)}{\partial \theta_i \partial \theta_i}}\right)\right)_{\mathbb{Z}}$ of the density p. The natural gradient is invariant under re-parameterization of the distribution.

A Monte-Carlo approximation reads

$$\widetilde{\nabla}_{\theta} \widehat{E}(\widehat{w}(f(\mathbf{x}))|\theta) = \sum_{i=1}^{\lambda} w_i F_{\theta}^{-1} \nabla_{\theta} \ln p(\mathbf{x}_{i:\lambda}|\theta), \quad w_i = \widehat{w}(f(\mathbf{x}_{i:\lambda})|\theta)$$

Theoretical Foundations

Maximum Likelihood Update

The new distribution mean m maximizes the log-likelihood

$$m_{\mathsf{new}} = \arg\max_{\mathbf{m}} \sum_{i=1}^{\mu} w_i \log p_{\mathcal{N}}(\mathbf{x}_{i:\lambda}|\mathbf{m})$$

independently of the given covariance matrix

The rank- μ update matrix \mathbf{C}_{μ} maximizes the log-likelihood

$$\mathbf{C}_{\mu} = \arg \max_{\mathbf{C}} \sum_{i=1}^{\mu} w_i \log p_{\mathcal{N}} \left(\frac{\mathbf{x}_{i:\lambda} - \mathbf{m}_{\mathsf{old}}}{\sigma} \middle| \mathbf{m}_{\mathsf{old}}, \mathbf{C} \right)$$

 $\log p_{\mathcal{N}}(\mathbf{x}|\mathbf{m}, \mathbf{C}) = -\frac{1}{2}\log \det(2\pi\mathbf{C}) - \frac{1}{2}(\mathbf{x} - \mathbf{m})^{\mathrm{T}}\mathbf{C}^{-1}(\mathbf{x} - \mathbf{m})$ $p_{\mathcal{N}}$ is the density of the multi-variate normal distribution
