# Problem Statement

## Continuous Domain Search/Optimization

- Task: **minimize** an **objective function** (*fitness function, loss function*) in continuous domain

$$f : \mathcal{X} \subseteq \mathbb{R}^n \rightarrow \mathbb{R}, \quad \mathbf{x} \mapsto f(\mathbf{x})$$

- **Black Box** scenario (direct search scenario)

- gradients are not available or not useful
- problem domain specific knowledge is used only within the black box, e.g. within an appropriate encoding
- Search **costs**: number of function evaluations

# Problem Statement

## Continuous Domain Search/Optimization

- Goal

- fast convergence to the global optimum

- solution  $x$  with **small function value**  $f(x)$  with **least search cost**  
... or to a robust solution  $x$   
there are two conflicting objectives

- Typical Examples

- shape optimization (e.g. using CFD)
- model calibration
- parameter calibration

curve fitting, airfoils  
biological, physical  
controller, plants, images

- Problems

- exhaustive search is infeasible
- naive random search takes too long
- deterministic search is not successful / takes too long

**Approach:** stochastic search, Evolutionary Algorithms

# Objective Function Properties

We assume  $f : \mathcal{X} \subset \mathbb{R}^n \rightarrow \mathbb{R}$  to be *non-linear, non-separable* and to have at least moderate dimensionality, say  $n \not\ll 10$ .

Additionally,  $f$  can be

- non-convex
- multimodal

there are possibly many local optima

- non-smooth

derivatives do not exist

- discontinuous, plateaus
- ill-conditioned
- noisy
- ...

**Goal** : cope with any of these function properties

they are related to real-world problems

# What Makes a Function Difficult to Solve?

Why stochastic search?

- non-linear, non-quadratic, non-convex  
on linear and quadratic functions much better search policies are available
- ruggedness  
non-smooth, discontinuous, multimodal, and/or noisy function
- dimensionality (size of search space)  
(considerably) larger than three
- non-separability  
dependencies between the objective variables
- ill-conditioning

gradient direction Newton direction

# Ruggedness

non-smooth, discontinuous, multimodal, and/or noisy

cut from a 5-D example, (easily) solvable with evolution strategies

# Curse of Dimensionality

The term *Curse of dimensionality* (Richard Bellman) refers to problems caused by the **rapid increase in volume** associated with adding extra dimensions to a (mathematical) space.

Example: Consider placing 100 points onto a real interval, say  $[0, 1]$ . To get **similar coverage**, in terms of distance between adjacent points, of the 10-dimensional space  $[0, 1]^{10}$  would require  $100^{10} = 10^{20}$  points. A 100 points appear now as isolated points in a vast empty space.

Remark: **distance measures** break down in higher dimensionalities (the central limit theorem kicks in)

Consequence: a **search policy** (e.g. exhaustive search) that is valuable in small dimensions **might be useless** in moderate or large dimensional search spaces.

# Separable Problems

## Definition (Separable Problem)

A function  $f$  is separable if

$$\arg \min_{(x_1, \dots, x_n)} f(x_1, \dots, x_n) = \left( \arg \min_{x_1} f(x_1, \dots), \dots, \arg \min_{x_n} f(\dots, x_n) \right)$$

⇒ it follows that  $f$  can be optimized in a sequence of  $n$  independent 1-D optimization processes

Example: Additively decomposable functions

$$f(x_1, \dots, x_n) = \sum_{i=1}^n f_i(x_i)$$

Rastrigin function

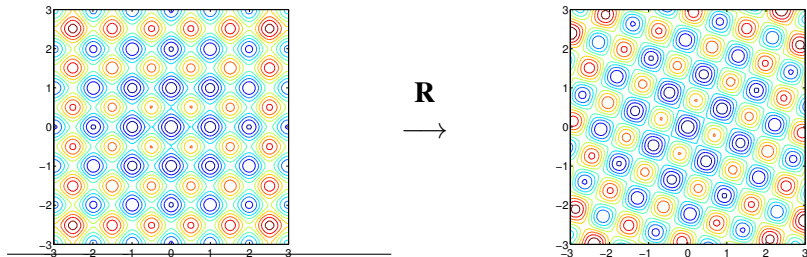

# Non-Separable Problems

Building a non-separable problem from a separable one <sup>(1,2)</sup>

## Rotating the coordinate system

- $f : \mathbf{x} \mapsto f(\mathbf{x})$  separable
- $f : \mathbf{x} \mapsto f(\mathbf{R}\mathbf{x})$  **non-separable**

$\mathbf{R}$  rotation matrix

<sup>1</sup> Hansen, Ostermeier, Gawelczyk (1995). On the adaptation of arbitrary normal mutation distributions in evolution strategies: The generating set adaptation. Sixth ICGA, pp. 57-64, Morgan Kaufmann

<sup>2</sup> Salomon (1996). "Reevaluating Genetic Algorithm Performance under Coordinate Rotation of Benchmark Functions; A survey of some theoretical and practical aspects of genetic algorithms." BioSystems, 39(3):263-278

# III-Conditioned Problems

## Curvature of level sets

Consider the convex-quadratic function

$$f(\mathbf{x}) = \frac{1}{2}(\mathbf{x} - \mathbf{x}^*)^T \mathbf{H}(\mathbf{x} - \mathbf{x}^*) = \frac{1}{2} \sum_i h_{i,i} x_i^2 + \frac{1}{2} \sum_{i \neq j} h_{i,j} x_i x_j$$

$\mathbf{H}$  is Hessian matrix of  $f$  and symmetric positive definite

gradient direction  $-f'(\mathbf{x})^T$

Newton direction  $-\mathbf{H}^{-1}f'(\mathbf{x})^T$

III-conditioning means **squeezed level sets** (high curvature).  
Condition number equals nine here. Condition numbers up to  $10^{10}$   
are not unusual in real world problems.

If  $\mathbf{H} \approx \mathbf{I}$  (small condition number of  $\mathbf{H}$ ) first order information (e.g. the gradient) is sufficient. Otherwise **second order information** (estimation of  $\mathbf{H}^{-1}$ ) **is necessary**.

# What Makes a Function Difficult to Solve?

... and what can be done

The Problem	Possible Approaches
Dimensionality	exploiting the problem structure separability, locality/neighborhood, encoding
Ill-conditioning	second order approach changes the neighborhood metric
Ruggedness	<b>non-local</b> policy, large sampling width (step-size) as large as possible while preserving a reasonable convergence speed  <b>population-based</b> method, stochastic, non-elitistic recombination operator serves as repair mechanism  restarts

# Stochastic Search

A black box search template to minimize  $f : \mathbb{R}^n \rightarrow \mathbb{R}$

**Initialize distribution parameters  $\theta$ , set population size  $\lambda \in \mathbb{N}$**

**While not terminate**

- ① **Sample distribution**  $P(x|\theta) \rightarrow x_1, \dots, x_\lambda \in \mathbb{R}^n$
- ② **Evaluate**  $x_1, \dots, x_\lambda$  on  $f$
- ③ **Update parameters**  $\theta \leftarrow F_\theta(\theta, x_1, \dots, x_\lambda, f(x_1), \dots, f(x_\lambda))$

Everything depends on the definition of  $P$  and  $F_\theta$

deterministic algorithms are covered as well

In many Evolutionary Algorithms the distribution  $P$  is implicitly defined via **operators on a population**, in particular, selection, recombination and mutation

Natural template for (incremental) *Estimation of Distribution Algorithms*

# The CMA-ES

**Input:**  $\mathbf{m} \in \mathbb{R}^n$ ,  $\sigma \in \mathbb{R}_+$ ,  $\lambda$

**Initialize:**  $\mathbf{C} = \mathbf{I}$ , and  $\mathbf{p}_c = \mathbf{0}$ ,  $\mathbf{p}_\sigma = \mathbf{0}$ ,

**Set:**  $c_c \approx 4/n$ ,  $c_\sigma \approx 4/n$ ,  $c_1 \approx 2/n^2$ ,  $c_\mu \approx \mu_w/n^2$ ,  $c_1 + c_\mu \leq 1$ ,  $d_\sigma \approx 1 + \sqrt{\frac{\mu_w}{n}}$ ,  
and  $w_{i=1\dots\lambda}$  such that  $\mu_w = \frac{1}{\sum_{i=1}^{\mu} w_i^2} \approx 0.3 \lambda$

**While not terminate**

$\mathbf{x}_i = \mathbf{m} + \sigma \mathbf{y}_i$ ,  $\mathbf{y}_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C})$ , for  $i = 1, \dots, \lambda$  sampling

$\mathbf{m} \leftarrow \sum_{i=1}^{\mu} w_i \mathbf{x}_{i:\lambda} = \mathbf{m} + \sigma \mathbf{y}_w$  where  $\mathbf{y}_w = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda}$  update mean

$\mathbf{p}_c \leftarrow (1 - c_c) \mathbf{p}_c + \mathbb{1}_{\{\|\mathbf{p}_\sigma\| < 1.5\sqrt{n}\}} \sqrt{1 - (1 - c_c)^2} \sqrt{\mu_w} \mathbf{y}_w$  cumulation for  $\mathbf{C}$

$\mathbf{p}_\sigma \leftarrow (1 - c_\sigma) \mathbf{p}_\sigma + \sqrt{1 - (1 - c_\sigma)^2} \sqrt{\mu_w} \mathbf{C}^{-\frac{1}{2}} \mathbf{y}_w$  cumulation for  $\sigma$

$\mathbf{C} \leftarrow (1 - c_1 - c_\mu) \mathbf{C} + c_1 \mathbf{p}_c \mathbf{p}_c^T + c_\mu \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda} \mathbf{y}_{i:\lambda}^T$  update  $\mathbf{C}$

$\sigma \leftarrow \sigma \times \exp\left(\frac{c_\sigma}{d_\sigma} \left(\frac{\|\mathbf{p}_\sigma\|}{\mathbb{E}\|\mathcal{N}(\mathbf{0}, \mathbf{I})\|} - 1\right)\right)$  update of  $\sigma$

**Not covered** on this slide: termination, restarts, useful output, boundaries and encoding

# Evolution Strategies

New search points are sampled normally distributed

$$\mathbf{x}_i \sim \mathbf{m} + \sigma \mathcal{N}_i(\mathbf{0}, \mathbf{C}) \quad \text{for } i = 1, \dots, \lambda$$

as perturbations of  $\mathbf{m}$ , where  $\mathbf{x}_i, \mathbf{m} \in \mathbb{R}^n$ ,  $\sigma \in \mathbb{R}_+$ ,  $\mathbf{C} \in \mathbb{R}^{n \times n}$

where

- the **mean** vector  $\mathbf{m} \in \mathbb{R}^n$  represents the favorite solution
- the so-called **step-size**  $\sigma \in \mathbb{R}_+$  controls the *step length*
- the **covariance matrix**  $\mathbf{C} \in \mathbb{R}^{n \times n}$  determines the **shape** of the distribution ellipsoid

here, all new points are sampled with the same parameters

The question remains how to update  $\mathbf{m}$ ,  $\mathbf{C}$ , and  $\sigma$ .

# Why Normal Distributions?

- 1 widely observed in nature, for example as phenotypic traits
- 2 only stable distribution with finite variance

stable means that the sum of normal variates is again normal:

$$\mathcal{N}(\mathbf{x}, \mathbf{A}) + \mathcal{N}(\mathbf{y}, \mathbf{B}) \sim \mathcal{N}(\mathbf{x} + \mathbf{y}, \mathbf{A} + \mathbf{B})$$

helpful in **design and analysis** of algorithms  
related to the *central limit theorem*

- 3 most convenient way to generate **isotropic** search points  
the isotropic distribution does **not favor any direction**, rotational invariant
- 4 maximum entropy distribution with finite variance  
the least possible assumptions on  $f$  in the distribution shape

# Normal Distribution

Standard Normal Distribution

probability density of the 1-D standard normal distribution

2-D Normal Distribution

probability density of a 2-D normal distribution

# The Multi-Variate ( $n$ -Dimensional) Normal Distribution

Any multi-variate normal distribution  $\mathcal{N}(\mathbf{m}, \mathbf{C})$  is uniquely determined by its mean value  $\mathbf{m} \in \mathbb{R}^n$  and its symmetric positive definite  $n \times n$  covariance matrix  $\mathbf{C}$ .

The **mean** value  $\mathbf{m}$

- determines the displacement (translation)
- value with the largest density (modal value)
- the distribution is symmetric about the distribution mean

The **covariance matrix**  $\mathbf{C}$

- determines the shape
- **geometrical interpretation:** any covariance matrix can be uniquely identified with the iso-density ellipsoid  $\{\mathbf{x} \in \mathbb{R}^n \mid (\mathbf{x} - \mathbf{m})^T \mathbf{C}^{-1} (\mathbf{x} - \mathbf{m}) = 1\}$

... any **covariance matrix** can be uniquely identified with the iso-density ellipsoid  
 $\{\mathbf{x} \in \mathbb{R}^n \mid (\mathbf{x} - \mathbf{m})^T \mathbf{C}^{-1} (\mathbf{x} - \mathbf{m}) = 1\}$

Lines of Equal Density

$\mathcal{N}(\mathbf{m}, \sigma^2 \mathbf{I}) \sim \mathbf{m} + \sigma \mathcal{N}(\mathbf{0}, \mathbf{I})$   
**one degree of freedom**  $\sigma$   
 components are  
 independent standard  
 normally distributed

$\mathcal{N}(\mathbf{m}, \mathbf{D}^2) \sim \mathbf{m} + \mathbf{D} \mathcal{N}(\mathbf{0}, \mathbf{I})$   
 **$n$  degrees of freedom**  
 components are  
 independent, scaled

$\mathcal{N}(\mathbf{m}, \mathbf{C}) \sim \mathbf{m} + \mathbf{C}^{\frac{1}{2}} \mathcal{N}(\mathbf{0}, \mathbf{I})$   
 **$(n^2 + n)/2$  degrees of freedom**  
 components are  
 correlated

where  $\mathbf{I}$  is the identity matrix (isotropic case) and  $\mathbf{D}$  is a diagonal matrix (reasonable for separable problems) and  $\mathbf{A} \times \mathcal{N}(\mathbf{0}, \mathbf{I}) \sim \mathcal{N}(\mathbf{0}, \mathbf{A}\mathbf{A}^T)$  holds for all  $\mathbf{A}$ .

# Effect of Dimensionality

$$\|\mathcal{N}(\mathbf{0}, \mathbf{I}) - \mathcal{N}(\mathbf{0}, \mathbf{I})\| / \sqrt{2} \sim \|\mathcal{N}(\mathbf{0}, \mathbf{I})\| \longrightarrow \mathcal{N}\left(\sqrt{n-1}/2, \mathbf{1}/2\right),$$

with modal value:  $\sqrt{n-1}$

yet: maximum entropy distribution

# Evolution Strategies

## Terminology

Let  $\mu$ : # of parents,  $\lambda$ : # of offspring

Plus (elitist) and comma (non-elitist) selection

$(\mu + \lambda)$ -ES: selection in  $\{\text{parents}\} \cup \{\text{offspring}\}$

$(\mu, \lambda)$ -ES: selection in  $\{\text{offspring}\}$

$(1 + 1)$ -ES

Sample one offspring from parent  $m$

$$\mathbf{x} = m + \sigma \mathcal{N}(\mathbf{0}, \mathbf{C})$$

If  $\mathbf{x}$  better than  $m$  select

$$m \leftarrow \mathbf{x}$$

...why?

# The $(\mu/\mu, \lambda)$ -ES

Non-elitist selection and intermediate (weighted) recombination

Given the  $i$ -th solution point  $\mathbf{x}_i = \mathbf{m} + \sigma \underbrace{\mathcal{N}_i(\mathbf{0}, \mathbf{C})}_{=: \mathbf{y}_i} = \mathbf{m} + \sigma \mathbf{y}_i$

Let  $\mathbf{x}_{i:\lambda}$  the  **$i$ -th ranked** solution point, such that  $f(\mathbf{x}_{1:\lambda}) \leq \dots \leq f(\mathbf{x}_{\lambda:\lambda})$ .  
The new mean reads

$$\mathbf{m} \leftarrow \sum_{i=1}^{\mu} w_i \mathbf{x}_{i:\lambda} = \mathbf{m} + \sigma \underbrace{\sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda}}_{=: \mathbf{y}_w}$$

where

$$w_1 \geq \dots \geq w_{\mu} > 0, \quad \sum_{i=1}^{\mu} w_i = 1, \quad \frac{1}{\sum_{i=1}^{\mu} w_i^2} =: \mu_w \approx \frac{\lambda}{4}$$

**The best  $\mu$  points** are selected from the new solutions (non-elitistic) and **weighted intermediate recombination** is applied.

# Invariance Under Monotonically Increasing Functions

## Rank-based algorithms

Update of all parameters uses only the ranks

$$f(x_{1:\lambda}) \leq f(x_{2:\lambda}) \leq \dots \leq f(x_{\lambda:\lambda})$$

$$g(f(x_{1:\lambda})) \leq g(f(x_{2:\lambda})) \leq \dots \leq g(f(x_{\lambda:\lambda})) \quad \forall g$$

$g$  is strictly monotonically increasing  
 $g$  preserves ranks

3

<sup>3</sup> Whitley 1989. The GENITOR algorithm and selection pressure: Why rank-based allocation of reproductive trials is best, ICGA

# Basic Invariance in Search Space

- translation invariance

is true for most optimization algorithms

$$f(\mathbf{x}) \leftrightarrow f(\mathbf{x} - \mathbf{a})$$

Identical behavior on  $f$  and  $f_a$

$$\begin{aligned} f &: \mathbf{x} \mapsto f(\mathbf{x}), & \mathbf{x}^{(t=0)} &= \mathbf{x}_0 \\ f_a &: \mathbf{x} \mapsto f(\mathbf{x} - \mathbf{a}), & \mathbf{x}^{(t=0)} &= \mathbf{x}_0 + \mathbf{a} \end{aligned}$$

No difference can be observed w.r.t. the argument of  $f$

# Rotational Invariance in Search Space

- invariance to orthogonal (rigid) transformations  $\mathbf{R}$ , where  $\mathbf{R}\mathbf{R}^T = \mathbf{I}$   
 e.g. true for simple evolution strategies  
 recombination operators might jeopardize rotational invariance

## Identical behavior on $f$ and $f_{\mathbf{R}}$

$$\begin{aligned}
 f &: \mathbf{x} \mapsto f(\mathbf{x}), & \mathbf{x}^{(t=0)} &= \mathbf{x}_0 \\
 f_{\mathbf{R}} &: \mathbf{x} \mapsto f(\mathbf{R}\mathbf{x}), & \mathbf{x}^{(t=0)} &= \mathbf{R}^{-1}(\mathbf{x}_0)
 \end{aligned}$$

45

No difference can be observed w.r.t. the argument of  $f$

# Invariance

*The grand aim of all science is to cover the greatest number of empirical facts by logical deduction from the smallest number of hypotheses or axioms.*

— Albert Einstein

- Empirical performance results, for example
  - from benchmark functions
  - from solved real world problems

are only useful if they do **generalize** to other problems

- **Invariance** is a strong **non-empirical** statement about generalization
  - generalizing (identical) performance from a single function to a whole class of functions

consequently, invariance is important for the evaluation of search algorithms

$$f(\mathbf{x}) = \sum_{i=1}^n x_i^2$$

in  $[-2.2, 0.8]^n$   
for  $n = 10$

# Why Step-Size Control?

(5/5<sub>w</sub>, 10)-ES, 11 runs

$$f(\mathbf{x}) = \sum_{i=1}^n x_i^2$$

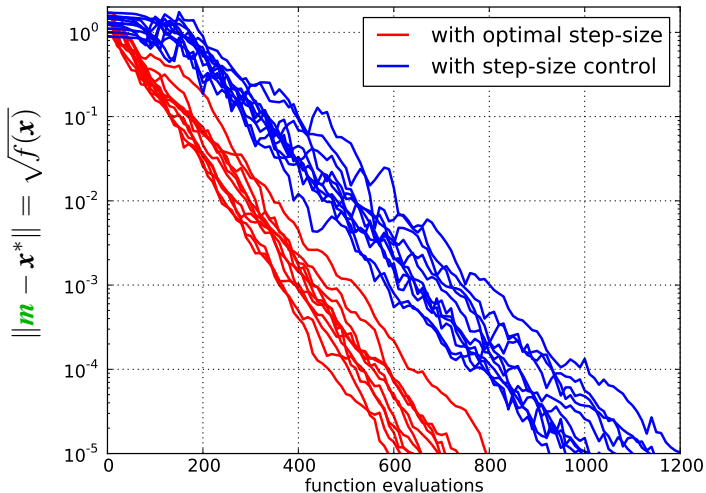

for  $n = 10$  and  
 $\mathbf{x}^0 \in [-0.2, 0.8]^n$

with optimal step-size  $\sigma$

# Why Step-Size Control?

(5/5<sub>w</sub>, 10)-ES, 2×11 runs

$$f(\mathbf{x}) = \sum_{i=1}^n x_i^2$$

for  $n = 10$  and  
 $\mathbf{x}^0 \in [-0.2, 0.8]^n$

with **optimal** versus **adaptive** step-size  $\sigma$  with too small initial  $\sigma$

# Why Step-Size Control?

(5/5<sub>w</sub>, 10)-ES

$$f(\mathbf{x}) = \sum_{i=1}^n x_i^2$$

for  $n = 10$  and  
 $\mathbf{x}^0 \in [-0.2, 0.8]^n$

comparing number of  $f$ -evals to reach  $\|m\| = 10^{-5}$ :  $\frac{1100-100}{650} \approx \mathbf{1.5}$

# Why Step-Size Control?

(5/5<sub>w</sub>, 10)-ES

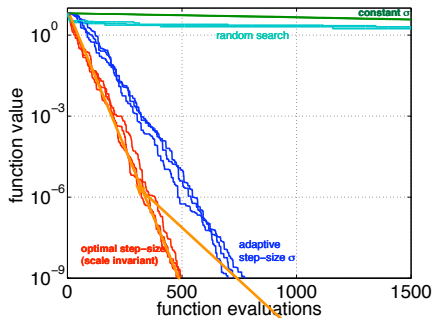

$$f(\mathbf{x}) = \sum_{i=1}^n x_i^2$$

in  $[-0.2, 0.8]^n$   
for  $n = 10$

comparing optimal versus default damping parameter  $d_\sigma: \frac{1700}{1100} \approx 1.5$

# Why Step-Size Control?

$$\sigma \leftarrow \sigma_{\text{opt}} \|\text{parent}\|$$

$$\frac{\varphi^*}{n}$$

$$\sigma_{\text{opt}}^*$$

$$\varphi^*$$

*evolution window* refers to the step-size interval (—) where reasonable performance is observed

# Methods for Step-Size Control

- **1/5-th success rule<sup>ab</sup>**, often applied with “+”-selection
  - increase step-size if more than 20% of the new solutions are successful, decrease otherwise
- **$\sigma$ -self-adaptation<sup>c</sup>**, applied with “,”-selection
  - mutation is applied to the step-size and the better, according to the objective function value, is selected
  - simplified “global” self-adaptation
- **path length control<sup>d</sup>** (Cumulative Step-size Adaptation, CSA)<sup>e</sup>
  - self-adaptation derandomized and non-localized

# One-fifth success rule

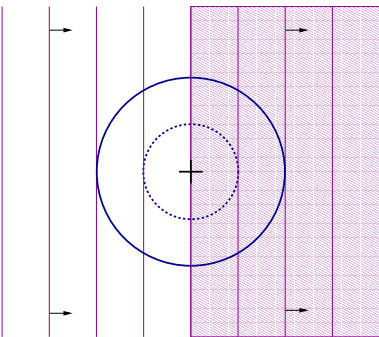

increase  $\sigma$

decrease  $\sigma$

# One-fifth success rule

Probability of success ( $p_s$ )

$1/2$

Probability of success ( $p_s$ )

"too small"

# One-fifth success rule

$p_s$ : # of successful offspring / # offspring (per generation)

$$\sigma \leftarrow \sigma \times \exp\left(\frac{1}{3} \times \frac{p_s - p_{\text{target}}}{1 - p_{\text{target}}}\right)$$

Increase  $\sigma$  if  $p_s > p_{\text{target}}$

Decrease  $\sigma$  if  $p_s < p_{\text{target}}$

## (1 + 1)-ES

$$p_{\text{target}} = 1/5$$

IF *offspring better parent*

$$p_s = 1, \sigma \leftarrow \sigma \times \exp(1/3)$$

ELSE

$$p_s = 0, \sigma \leftarrow \sigma / \exp(1/3)^{1/4}$$

# Path Length Control (CSA)

## The Concept of Cumulative Step-Size Adaptation

$$x_i = m + \sigma y_i$$

$$m \leftarrow m + \sigma y_w$$

Measure the length of the *evolution path*

the pathway of the mean vector  $m$  in the generation sequence

loosely speaking steps are

- perpendicular under random selection (in expectation)
- perpendicular in the desired situation (to be most efficient)

# Path Length Control (CSA)

## The Equations

Initialize  $\mathbf{m} \in \mathbb{R}^n$ ,  $\sigma \in \mathbb{R}_+$ , evolution path  $\mathbf{p}_\sigma = \mathbf{0}$ ,  
set  $c_\sigma \approx 4/n$ ,  $d_\sigma \approx 1$ .

$$\mathbf{m} \leftarrow \mathbf{m} + \sigma \mathbf{y}_w \quad \text{where } \mathbf{y}_w = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda} \quad \text{update mean}$$

$$\mathbf{p}_\sigma \leftarrow (1 - c_\sigma) \mathbf{p}_\sigma + \underbrace{\sqrt{1 - (1 - c_\sigma)^2}}_{\text{accounts for } 1 - c_\sigma} \underbrace{\sqrt{\mu_w}}_{\text{accounts for } w_i} \mathbf{y}_w$$

$$\sigma \leftarrow \sigma \times \underbrace{\exp\left(\frac{c_\sigma}{d_\sigma} \left(\frac{\|\mathbf{p}_\sigma\|}{\mathbb{E}\|\mathcal{N}(\mathbf{0}, \mathbf{I})\|} - 1\right)\right)}_{>1 \iff \|\mathbf{p}_\sigma\| \text{ is greater than its expectation}} \quad \text{update step-size}$$

## (5/5, 10)-CSA-ES, default parameters

$$f(\mathbf{x}) = \sum_{i=1}^n x_i^2$$

in  $[-0.2, 0.8]^n$   
for  $n = 30$

where

- the **mean** vector  $\mathbf{m} \in \mathbb{R}^n$  represents the favorite solution
- the so-called **step-size**  $\sigma \in \mathbb{R}_+$  controls the *step length*
- the **covariance matrix**  $\mathbf{C} \in \mathbb{R}^{n \times n}$  determines the **shape** of the distribution ellipsoid

The remaining question is how to update  $\mathbf{C}$ .

# Covariance Matrix Adaptation

## Rank-One Update

$$\mathbf{m} \leftarrow \mathbf{m} + \sigma \mathbf{y}_w, \quad \mathbf{y}_w = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda}, \quad \mathbf{y}_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$

new distribution,

$$\mathbf{C} \leftarrow 0.8 \times \mathbf{C} + 0.2 \times \mathbf{y}_w \mathbf{y}_w^T$$

the ruling principle: the adaptation **increases the likelihood of successful steps**,  $\mathbf{y}_w$ , to appear again

another viewpoint: the adaptation **follows a natural gradient**

approximation of the expected fitness

... equations

# Covariance Matrix Adaptation

## Rank-One Update

Initialize  $\mathbf{m} \in \mathbb{R}^n$ , and  $\mathbf{C} = \mathbf{I}$ , set  $\sigma = 1$ , learning rate  $c_{\text{cov}} \approx 2/n^2$

While not terminate

$$\mathbf{x}_i = \mathbf{m} + \sigma \mathbf{y}_i, \quad \mathbf{y}_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C}),$$

$$\mathbf{m} \leftarrow \mathbf{m} + \sigma \mathbf{y}_w \quad \text{where } \mathbf{y}_w = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda}$$

$$\mathbf{C} \leftarrow (1 - c_{\text{cov}})\mathbf{C} + c_{\text{cov}} \underbrace{\mu_w \mathbf{y}_w \mathbf{y}_w^T}_{\text{rank-one}} \quad \text{where } \mu_w = \frac{1}{\sum_{i=1}^{\mu} w_i^2} \geq 1$$

The rank-one update has been found independently in several domains<sup>6 7 8 9</sup>

# Cumulation

## The Evolution Path

### Evolution Path

Conceptually, the evolution path is the **search path** the strategy takes **over a number of generation steps**. It can be expressed as a sum of consecutive *steps* of the mean  $m$ .

An exponentially weighted sum of steps  $y_w$  is used

$$p_c \propto \sum_{i=0}^g \underbrace{(1 - c_c)^{g-i}}_{\text{exponentially fading weights}} y_w^{(i)}$$

The recursive construction of the evolution path (cumulation):

$$p_c \leftarrow \underbrace{(1 - c_c)}_{\text{decay factor}} p_c + \underbrace{\sqrt{1 - (1 - c_c)^2} \sqrt{\mu_w}}_{\text{normalization factor}} \underbrace{y_w}_{\text{input} = \frac{m - m_{\text{old}}}{\sigma}}$$

where  $\mu_w = \frac{1}{\sum w_i^2}$ ,  $c_c \ll 1$ . **History information** is accumulated in the evolution path.

“Cumulation” is a widely used technique and also know as

- *exponential smoothing* in time series, forecasting
- exponentially weighted *moving average*
- *iterate averaging* in stochastic approximation
- *momentum* in the back-propagation algorithm for ANNs
- ...

“Cumulation” conducts a *low-pass* filtering, but there is more to it. . .

...why?

# Cumulation

## Utilizing the Evolution Path

We used  $\mathbf{y}_w \mathbf{y}_w^T$  for updating  $\mathbf{C}$ . Because  $\mathbf{y}_w \mathbf{y}_w^T = -\mathbf{y}_w (-\mathbf{y}_w)^T$  the sign of  $\mathbf{y}_w$  is lost.

The **sign information** (signifying correlation *between* steps) is (re-)introduced by using the *evolution path*.

$$\begin{aligned}
 \mathbf{p}_c &\leftarrow \underbrace{(1 - c_c)}_{\text{decay factor}} \mathbf{p}_c + \underbrace{\sqrt{1 - (1 - c_c)^2}}_{\text{normalization factor}} \sqrt{\mu_w} \mathbf{y}_w \\
 \mathbf{C} &\leftarrow (1 - c_{\text{cov}}) \mathbf{C} + c_{\text{cov}} \underbrace{\mathbf{p}_c \mathbf{p}_c^T}_{\text{rank-one}}
 \end{aligned}$$

where  $\mu_w = \frac{1}{\sum w_i^2}$ ,  $c_{\text{cov}} \ll c_c \ll 1$  such that  $1/c_c$  is the “backward time horizon”.

Using an **evolution path** for the **rank-one update** of the covariance matrix reduces the number of function evaluations to adapt to a straight ridge **from about  $\mathcal{O}(n^2)$  to  $\mathcal{O}(n)$** .<sup>(a)</sup>

<sup>a</sup>Hansen, Müller and Koumoutsakos 2003. Reducing the Time Complexity of the Derandomized Evolution Strategy with Covariance Matrix Adaptation (CMA-ES). *Evolutionary Computation*, 11(1), pp. 1-18

Number of  $f$ -evaluations divided by dimension on the cigar function  $f(\mathbf{x}) = x_1^2 + 10^6 \sum_{i=2}^n x_i^2$

The overall model complexity is  $n^2$  but important parts of the model can be learned in time of order  $n$

# Rank- $\mu$ Update

$$\begin{aligned} \mathbf{x}_i &= \mathbf{m} + \sigma \mathbf{y}_i, & \mathbf{y}_i &\sim \mathcal{N}_i(\mathbf{0}, \mathbf{C}), \\ \mathbf{m} &\leftarrow \mathbf{m} + \sigma \mathbf{y}_w & \mathbf{y}_w &= \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda} \end{aligned}$$

The rank- $\mu$  update extends the update rule for **large population sizes**  $\lambda$  using  $\mu > 1$  vectors to update  $\mathbf{C}$  at each generation step.

The weighted empirical covariance matrix

$$\mathbf{C}_{\mu} = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda} \mathbf{y}_{i:\lambda}^T$$

computes a weighted mean of the outer products of the best  $\mu$  steps and has rank  $\min(\mu, n)$  with probability one.

with  $\mu = \lambda$  weights can be negative <sup>10</sup>

The rank- $\mu$  update then reads

$$\mathbf{C} \leftarrow (1 - c_{\text{cov}}) \mathbf{C} + c_{\text{cov}} \mathbf{C}_{\mu}$$

where  $c_{\text{cov}} \approx \mu_w/n^2$  and  $c_{\text{cov}} \leq 1$ .

<sup>10</sup> Jastrebski and Arnold (2006). Improving evolution strategies through active covariance matrix adaptation. CEC.

$$x_i = m + \sigma y_i, \quad y_i \sim \mathcal{N}(\mathbf{0}, \mathbf{C})$$

$$\begin{aligned} \mathbf{C}_\mu &= \frac{1}{\mu} \sum y_{i:\lambda} y_{i:\lambda}^T \\ \mathbf{C} &\leftarrow \frac{1}{(1-\lambda)} \times \mathbf{C} + \lambda \times \mathbf{C}_\mu \end{aligned}$$

$$m_{\text{new}} \leftarrow m + \frac{1}{\mu} \sum y_{i:\lambda}$$

<sup>11</sup> Hansen, N. (2006). The CMA Evolution Strategy: A Comparing Review. In J.A. Lozano, P. Larranga, I. Inza and E. Bengoetxea (Eds.). Towards a new evolutionary computation. Advances in estimation of distribution algorithms. pp. 75-102

## The rank- $\mu$ update

- increases the possible learning rate in large populations  
roughly from  $2/n^2$  to  $\mu_w/n^2$
- can reduce the number of necessary **generations** roughly from  $\mathcal{O}(n^2)$  to  $\mathcal{O}(n)$  <sup>(12)</sup>  
given  $\mu_w \propto \lambda \propto n$

Therefore the rank- $\mu$  update is the primary mechanism whenever a large population size is used

say  $\lambda \geq 3n + 10$

## The rank-one update

- uses the evolution path and reduces the number of necessary **function evaluations** to learn straight ridges from  $\mathcal{O}(n^2)$  to  $\mathcal{O}(n)$ .

Rank-one update and rank- $\mu$  update can be combined

... all equations

---

# Summary of Equations

## The Covariance Matrix Adaptation Evolution Strategy

**Input:**  $\mathbf{m} \in \mathbb{R}^n$ ,  $\sigma \in \mathbb{R}_+$ ,  $\lambda$

**Initialize:**  $\mathbf{C} = \mathbf{I}$ , and  $\mathbf{p}_c = \mathbf{0}$ ,  $\mathbf{p}_\sigma = \mathbf{0}$ ,

**Set:**  $c_c \approx 4/n$ ,  $c_\sigma \approx 4/n$ ,  $c_1 \approx 2/n^2$ ,  $c_\mu \approx \mu_w/n^2$ ,  $c_1 + c_\mu \leq 1$ ,  $d_\sigma \approx 1 + \sqrt{\frac{\mu_w}{n}}$ ,  
and  $w_{i=1\dots\lambda}$  such that  $\mu_w = \frac{1}{\sum_{i=1}^\mu w_i^2} \approx 0.3 \lambda$

**While not terminate**

$\mathbf{x}_i = \mathbf{m} + \sigma \mathbf{y}_i$ ,  $\mathbf{y}_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C})$ , for  $i = 1, \dots, \lambda$  sampling

$\mathbf{m} \leftarrow \sum_{i=1}^\mu w_i \mathbf{x}_{i:\lambda} = \mathbf{m} + \sigma \mathbf{y}_w$  where  $\mathbf{y}_w = \sum_{i=1}^\mu w_i \mathbf{y}_{i:\lambda}$  update mean

$\mathbf{p}_c \leftarrow (1 - c_c) \mathbf{p}_c + \mathbb{1}_{\{\|\mathbf{p}_\sigma\| < 1.5\sqrt{n}\}} \sqrt{1 - (1 - c_c)^2} \sqrt{\mu_w} \mathbf{y}_w$  cumulation for  $\mathbf{C}$

$\mathbf{p}_\sigma \leftarrow (1 - c_\sigma) \mathbf{p}_\sigma + \sqrt{1 - (1 - c_\sigma)^2} \sqrt{\mu_w} \mathbf{C}^{-\frac{1}{2}} \mathbf{y}_w$  cumulation for  $\sigma$

$\mathbf{C} \leftarrow (1 - c_1 - c_\mu) \mathbf{C} + c_1 \mathbf{p}_c \mathbf{p}_c^T + c_\mu \sum_{i=1}^\mu w_i \mathbf{y}_{i:\lambda} \mathbf{y}_{i:\lambda}^T$  update  $\mathbf{C}$

$\sigma \leftarrow \sigma \times \exp\left(\frac{c_\sigma}{d_\sigma} \left(\frac{\|\mathbf{p}_\sigma\|}{\mathbb{E}\|\mathcal{N}(\mathbf{0}, \mathbf{I})\|} - 1\right)\right)$  update of  $\sigma$

**Not covered** on this slide: termination, restarts, useful output, boundaries and encoding

## Source Code Snippet

The image shows a web browser window with the address bar displaying 'http://en.wikipedia.org/wiki/CMA-ES'. The main content area shows a snippet of MATLAB code for the CMA-ES algorithm. The code is color-coded and includes comments explaining various steps like generating offspring, sorting by fitness, updating the mean, and adapting the covariance matrix and step size.

```

counteval = 0; % the next 40 lines contain the 20 lines of interesting code
while counteval < stopeval

    % Generate and evaluate lambda offspring
    for k=1:lambda,
        arx(:,k) = xmean + sigma * B * (D .* randn(N,1)); % m + sig * Normal(0,C)
        arfitness(k) = feval(strfitnessfct, arx(:,k)); % objective function call
        counteval = counteval+1;
    end

    % Sort by fitness and compute weighted mean into xmean
    [arfitness, arindex] = sort(arfitness); % minimization
    xold = xmean;
    xmean = arx(:,arindex(1:mu))*weights; % recombination, new mean value

    % Cumulation: Update evolution paths

# Strategy Internal Parameters

- related to selection and recombination
  - $\lambda$ , offspring number, new solutions sampled, population size
  - $\mu$ , parent number, solutions involved in updates of  $m$ ,  $C$ , and  $\sigma$
  - $w_{i=1, \dots, \mu}$ , recombination weights  
 $\mu$  and  $w_i$  should be chosen such that the variance effective selection mass  $\mu_w \approx \frac{\lambda}{4}$ , where  $\mu_w := 1 / \sum_{i=1}^{\mu} w_i^2$ .
- related to  $C$ -update
  - $c_c$ , decay rate for the evolution path
  - $c_1$ , learning rate for rank-one update of  $C$
  - $c_\mu$ , learning rate for rank- $\mu$  update of  $C$
- related to  $\sigma$ -update
  - $c_\sigma$ , decay rate of the evolution path
  - $d_\sigma$ , damping for  $\sigma$ -change

Parameters were identified in carefully chosen experimental set ups. **Parameters do not in the first place depend on the objective function** and are not meant to be in the users choice. Only(?) the population size  $\lambda$  might be reasonably varied in a wide range, *depending on the objective function*

Useful: restarts with increasing population size (IPOP)

# Experimentum Crucis (0)

What did we want to achieve?

- reduce any convex-quadratic function

$$f(\mathbf{x}) = \mathbf{x}^T \mathbf{H} \mathbf{x}$$

e.g.  $f(\mathbf{x}) = \sum_{i=1}^n 10^{6 \frac{i-1}{n-1}} x_i^2$

to the sphere model

$$f(\mathbf{x}) = \mathbf{x}^T \mathbf{x}$$

without use of derivatives

- lines of equal density align with lines of equal fitness

$$\mathbf{C} \propto \mathbf{H}^{-1}$$

in a stochastic sense

# Experimentum Crucis (1)

$f$  convex quadratic, separable

blue: abs(f), cyan:  $f - \min(f)$ , green: sigma, red: axis ratio

Object Variables (9-D)

Principle Axes Lengths

Standard Deviations in Coordinates divided by sigma

$$f(\mathbf{x}) = \sum_{i=1}^n 10^{\alpha \frac{i-1}{n-1}} x_i^2, \alpha = 6$$

# Experimentum Crucis (2)

$f$  convex quadratic, as before but non-separable (rotated)

$C \propto H^{-1}$  for all  $g, H$

$f(x) = g(x^T H x)$ ,  $g : \mathbb{R} \rightarrow \mathbb{R}$  strictly increasing

# Natural Gradient Descent

- Consider  $\arg \min_{\theta} E(f(\mathbf{x})|\theta)$  under the sampling distribution  $\mathbf{x} \sim p(\cdot|\theta)$  we could improve  $E(f(\mathbf{x})|\theta)$  by following the gradient  $\nabla_{\theta} E(f(\mathbf{x})|\theta)$ :

$$\theta \leftarrow \theta - \eta \nabla_{\theta} E(f(\mathbf{x})|\theta), \quad \eta > 0$$

$\nabla_{\theta}$  depends on the parameterization of the distribution, therefore

- Consider the **natural gradient** of the expected transformed fitness

$$\begin{aligned} \tilde{\nabla}_{\theta} E(w \circ P_f(f(\mathbf{x}))|\theta) &= F_{\theta}^{-1} \nabla_{\theta} E(w \circ P_f(f(\mathbf{x}))|\theta) \\ &= E(w \circ P_f(f(\mathbf{x})) F_{\theta}^{-1} \nabla_{\theta} \ln p(\mathbf{x}|\theta)) \end{aligned}$$

using the Fisher information matrix  $F_{\theta} = \left( \left( E \frac{\partial^2 \log p(\mathbf{x}|\theta)}{\partial \theta_i \partial \theta_j} \right) \right)_{ij}$  of the density  $p$ .

The natural gradient is **invariant under re-parameterization** of the distribution.

- A **Monte-Carlo approximation** reads

$$\tilde{\nabla}_{\theta} \hat{E}(\hat{w}(f(\mathbf{x}))|\theta) = \sum_{i=1}^{\lambda} w_i F_{\theta}^{-1} \nabla_{\theta} \ln p(\mathbf{x}_{i:\lambda}|\theta), \quad w_i = \hat{w}(f(\mathbf{x}_{i:\lambda})|\theta)$$

# CMA-ES – Cumulation = Natural Evolution Strategy

Natural gradient descend using the MC approximation and the normal distribution

- Rewriting the update of the distribution mean

$$\mathbf{m}_{\text{new}} \leftarrow \sum_{i=1}^{\mu} w_i \mathbf{x}_{i:\lambda} = \mathbf{m} + \underbrace{\sum_{i=1}^{\mu} w_i (\mathbf{x}_{i:\lambda} - \mathbf{m})}_{\text{natural gradient for mean } \frac{\partial}{\partial \mathbf{m}} \widehat{\mathbb{E}}(w \circ P_f(f(\mathbf{x})) | \mathbf{m}, \mathbf{C})}$$

- Rewriting the update of the covariance matrix<sup>13</sup>

$$\begin{aligned} \mathbf{C}_{\text{new}} \leftarrow & \mathbf{C} + c_1 \overbrace{(\mathbf{p}_c \mathbf{p}_c^T)}^{\text{rank one}} - \mathbf{C} \\ & + \frac{c_\mu}{\sigma^2} \sum_{i=1}^{\mu} w_i \underbrace{\left( (\mathbf{x}_{i:\lambda} - \mathbf{m}) (\mathbf{x}_{i:\lambda} - \mathbf{m})^T - \sigma^2 \mathbf{C} \right)}_{\text{rank-}\mu} \\ & \text{natural gradient for covariance matrix } \frac{\partial}{\partial \mathbf{C}} \widehat{\mathbb{E}}(w \circ P_f(f(\mathbf{x})) | \mathbf{m}, \mathbf{C}) \end{aligned}$$

<sup>13</sup> Akimoto et al. (2010): Bidirectional Relation between CMA Evolution Strategies and Natural Evolution

# Maximum Likelihood Update

The new distribution mean  $\mathbf{m}$  maximizes the log-likelihood

$$\mathbf{m}_{\text{new}} = \arg \max_{\mathbf{m}} \sum_{i=1}^{\mu} w_i \log p_{\mathcal{N}}(\mathbf{x}_{i:\lambda} | \mathbf{m})$$

independently of the given covariance matrix

The rank- $\mu$  update matrix  $\mathbf{C}_{\mu}$  maximizes the log-likelihood

$$\mathbf{C}_{\mu} = \arg \max_{\mathbf{C}} \sum_{i=1}^{\mu} w_i \log p_{\mathcal{N}} \left( \frac{\mathbf{x}_{i:\lambda} - \mathbf{m}_{\text{old}}}{\sigma} \mid \mathbf{m}_{\text{old}}, \mathbf{C} \right)$$

$$\log p_{\mathcal{N}}(\mathbf{x} | \mathbf{m}, \mathbf{C}) = -\frac{1}{2} \log \det(2\pi\mathbf{C}) - \frac{1}{2}(\mathbf{x} - \mathbf{m})^{\text{T}}\mathbf{C}^{-1}(\mathbf{x} - \mathbf{m})$$

$p_{\mathcal{N}}$  is the density of the multi-variate normal distribution

# Variable Metric

On the function class

$$f(\mathbf{x}) = g \left( \frac{1}{2}(\mathbf{x} - \mathbf{x}^*)\mathbf{H}(\mathbf{x} - \mathbf{x}^*)^T \right)$$

the covariance matrix approximates the inverse Hessian up to a constant factor, that is:

$$\mathbf{C} \propto \mathbf{H}^{-1} \quad (\text{approximately})$$

In effect, ellipsoidal level-sets are transformed into spherical level-sets.

$g : \mathbb{R} \rightarrow \mathbb{R}$  is strictly increasing

# On Convergence

Evolution Strategies converge with probability one on,  
e.g.,  $g\left(\frac{1}{2}\mathbf{x}^T\mathbf{H}\mathbf{x}\right)$  like

$$\|\mathbf{m}_k - \mathbf{x}^*\| \propto e^{-ck}, \quad c \leq \frac{0.25}{n}$$

Monte Carlo pure random search converges like

$$\|\mathbf{m}_k - \mathbf{x}^*\| \propto k^{-c} = e^{-c \log k}, \quad c = \frac{1}{n}$$

# Comparison during BBOB at GECCO 2010

24 functions and 20+ algorithms in 20-D

# Comparison during BBOB at GECCO 2009

30 **noisy** functions and 20 algorithms in 20-D

# Comparison during BBOB at GECCO 2010

30 **noisy** functions and 10+ algorithms in 20-D

- 1 Problem Statement
- 2 Evolution Strategies
- 3 Step-Size Control
- 4 Covariance Matrix Adaptation
- 5 CMA-ES Summary
- 6 Theoretical Foundations
- 7 Comparing Experiments
- 8 Summary and Final Remarks**

# The Continuous Search Problem

**Difficulties** of a non-linear optimization problem are

- dimensionality and non-separability

demands to exploit problem structure, e.g. neighborhood  
cave: design of benchmark functions

- ill-conditioning

demands to acquire a second order model

- ruggedness

demands a non-local (stochastic? population based?) approach

# Main Characteristics of (CMA) Evolution Strategies

- ① Multivariate normal distribution to generate new search points  
follows the maximum entropy principle
- ② Rank-based selection  
implies invariance, same performance on  $g(f(x))$  for any increasing  $g$   
more invariance properties are featured
- ③ Step-size control facilitates fast (log-linear) convergence and possibly linear scaling with the dimension  
in CMA-ES based on an **evolution path** (a non-local trajectory)
- ④ *Covariance matrix adaptation (CMA)* **increases the likelihood of previously successful steps** and can improve performance by orders of magnitude  
the update follows the natural gradient  
 $\mathbf{C} \propto \mathbf{H}^{-1} \iff$  adapts a variable metric  
 $\iff$  new (rotated) problem representation  
 $\implies f : \mathbf{x} \mapsto g(\mathbf{x}^T \mathbf{H} \mathbf{x})$  reduces to  $\mathbf{x} \mapsto \mathbf{x}^T \mathbf{x}$

# Limitations

## of CMA Evolution Strategies

- **internal CPU-time:**  $10^{-8}n^2$  seconds per function evaluation on a 2GHz PC, tweaks are available  
     1 000 000  $f$ -evaluations in 100-D take 100 seconds *internal CPU-time*
- better methods are presumably available in case of
  - partly separable problems
  - specific problems, for example with cheap gradients  
     *specific methods*
  - small dimension ( $n \ll 10$ )  
     *for example Nelder-Mead*
  - small running times (number of  $f$ -evaluations  $< 100n$ )  
     *model-based methods*

# Thank You

Source code for CMA-ES in C, Java, Matlab, Octave, Python, Scilab is available at [http://www.lri.fr/~hansen/cmaes\\_inmatlab.html](http://www.lri.fr/~hansen/cmaes_inmatlab.html)
