Volatility Not Constant

Skews of Implied Volatilities (SP500 on June 1, 2007)

What's Wrong with Heston?

- Single factor of volatility running on single time scale not sufficient to describe dynamics of the volatility process.
- Not just Heston . . . Any one-factor stochastic volatility model has trouble fitting implied volatility levels across all strikes and maturities.
- Empirical evidence suggests existence of several stochastic volatility factors running on different time scales
- →

Multiscale SV Under Risk-Neutral

$$dX_t = rX_t dt + f(Y_t, Z_t)X_t dW_t^{(0)*},$$

$$dY_t = \left(\frac{1}{\varepsilon} \alpha(Y_t) - \frac{1}{\sqrt{\varepsilon}} \beta(Y_t) \Lambda_1(Y_t, Z_t) \right) dt + \frac{1}{\sqrt{\varepsilon}} \beta(Y_t) dW_t^{(1)*},$$

$$dZ_t = \left(\delta c(Z_t) - \sqrt{\delta} g(Z_t) \Lambda_2(Y_t, Z_t) \right) dt + \sqrt{\delta} g(Z_t) dW_t^{(2)*}.$$

Time scales: $\varepsilon \ll 1 \ll 1/\delta$

Fast factor: Y

Slow factor: Z

Option pricing:

$$P^{\varepsilon, \delta}(t, X_t, Y_t, Z_t) = \mathbf{E}^* \left\{ e^{-r(T-t)} h(X_T) \mid X_t, Y_t, Z_t \right\},$$

$$\frac{\partial P^{\varepsilon, \delta}}{\partial t} + \mathcal{L}_{(X, Y, Z)} P^{\varepsilon, \delta} - rP^{\varepsilon, \delta} = 0.$$

Expand

$$P^{\varepsilon, \delta} = \sum_{i \geq 0} \sum_{j \geq 0} (\sqrt{\varepsilon})^i (\sqrt{\delta})^j P_{i,j},$$

$P_0 = P_{BS}$ computed at volatility $\sigma(z)$:

$$\bar{\sigma}^2(z) = \langle f^2(\cdot, z) \rangle = \int f^2(y, z) \Phi_Y(dy).$$

$$\sqrt{\varepsilon} P_{1,0} = V_2^\varepsilon x^2 \frac{\partial^2 P_{BS}}{\partial x^2} + V_3^\varepsilon x \frac{\partial}{\partial x} \left(x^2 \frac{\partial^2 P_{BS}}{\partial x^2} \right),$$

$$\sqrt{\delta} P_{0,1} = V_0^\delta \frac{\partial P_{BS}}{\partial \sigma} + V_1^\delta \frac{\partial}{\partial x} \left(\frac{\partial P_{BS}}{\partial \sigma} \right).$$

In terms of implied volatility:

$$I \approx (b^* + \tau b^\delta) + (a^\varepsilon + \tau a^\delta) \frac{\log(K/x)}{\tau}, \quad \tau = T - t.$$

Time Scales

The previous asymptotics is a perturbation around Black-Scholes leading to Black-Scholes 2.0 where $2.0 = 1 + 2 \times (0.5)$

Why not keeping one volatility factor on a time scale of order one? This would be a perturbation around a one-factor stochastic volatility model, but which one?

Heston of course!

Heston Under Risk-Neutral Measure

$$\begin{aligned}dX_t &= rX_t dt + \sqrt{Z_t} X_t dW_t^x \\dZ_t &= \kappa(\theta - Z_t) dt + \sigma \sqrt{Z_t} dW_t^z \\d\langle W^x, W^z \rangle_t &= \rho dt\end{aligned}$$

- One-factor stochastic volatility model
- Square of volatility, Z_t , follows CIR process

Formulas!

- Explicit formulas for european options:

$$P_H(t, x, z) = e^{-r\tau} \frac{1}{2\pi} \int e^{-ikq} \widehat{G}(\tau, k, z) \widehat{h}(k) dk$$

$$q(t, x) = r(T - t) + \log x,$$

$$\widehat{h}(k) = \int e^{ikq} h(e^q) dq,$$

$$\widehat{G}(\tau, k, z) = e^{C(\tau, k) + zD(\tau, k)}$$

- $C(\tau, k)$ and $D(\tau, k)$ solve ODEs in $\tau = T - t$.

ODEs

$$\begin{aligned}\frac{dD}{d\tau}(\tau, k) &= \frac{1}{2}\sigma^2 D^2(\tau, k) - (\kappa + \rho\sigma ik) D(\tau, k) + \frac{1}{2}(-k^2 + ik), \\ D(0, k) &= 0.\end{aligned}$$

$$\begin{aligned}\frac{dC}{d\tau}(\tau, k) &= \kappa\theta D(\tau, k), \\ C(0, k) &= 0,\end{aligned}$$

Pretty Pictures! Heston captures well-documented features of implied volatility surface: smile and skew

Multiscale Under Risk-Neutral Measure

$$\begin{aligned}dX_t &= rX_t dt + \sqrt{Z_t} f(Y_t) X_t dW_t^x \\dY_t &= \frac{Z_t}{\varepsilon} (m - Y_t) dt + \nu \sqrt{2} \sqrt{\frac{Z_t}{\varepsilon}} dW_t^y \\dZ_t &= \kappa(\theta - Z_t) dt + \sigma \sqrt{Z_t} dW_t^z \\d\langle W^i, W^j \rangle_t &= \rho_{ij} dt \quad i, j \in \{x, y, z\}\end{aligned}$$

- Volatility controlled by product $\sqrt{Z_t} f(Y_t)$
- Y_t modeled as OU process running on time-scale ε/Z_t
- Note: $f(y) = 1 \Rightarrow$ model reduces to Heston

Option Pricing PDE

- Price of European Option Expressed as

$$P_t = \mathbb{E} \left[e^{-r(T-t)} h(X_T) \mid X_t, Y_t, Z_t \right] =: P^\varepsilon(t, X_t, Y_t, Z_t)$$

- Using Feynman-Kac, derive following PDE for P^ε

$$\mathcal{L}^\varepsilon P^\varepsilon(t, x, y, z) = 0,$$

$$\mathcal{L}^\varepsilon = \frac{\partial}{\partial t} + \mathcal{L}_{(X,Y,Z)} - r,$$

$$P^\varepsilon(T, x, y, z) = h(x)$$

Some Book-Keeping of \mathcal{L}^ε

- \mathcal{L}^ε has convenient form (z factorizes)

$$\mathcal{L}^\varepsilon = \frac{z}{\varepsilon} \mathcal{L}_0 + \frac{z}{\sqrt{\varepsilon}} \mathcal{L}_1 + \mathcal{L}_2,$$

$$\mathcal{L}_0 = \nu^2 \frac{\partial^2}{\partial y^2} + (m - y) \frac{\partial}{\partial y}$$

$$\mathcal{L}_1 = \rho_{yz} \sigma \nu \sqrt{2} \frac{\partial^2}{\partial y \partial z} + \rho_{xy} \nu \sqrt{2} f(y) x \frac{\partial^2}{\partial x \partial y}$$

$$\begin{aligned} \mathcal{L}_2 = & \frac{\partial}{\partial t} + \frac{1}{2} f^2(y) z x^2 \frac{\partial^2}{\partial x^2} + r \left(x \frac{\partial}{\partial x} - \cdot \right) \\ & + \frac{1}{2} \sigma^2 z \frac{\partial^2}{\partial z^2} + \kappa (\theta - z) \frac{\partial}{\partial z} + \rho_{xz} \sigma f(y) z x \frac{\partial^2}{\partial x \partial z}. \end{aligned}$$

Expand

- Perform singular perturbation with respect to ε

$$P^\varepsilon = P_0 + \sqrt{\varepsilon}P_1 + \varepsilon P_2 + \dots$$

- Look for P_0 and P_1 functions of t , x , and z only
- Find

$$P_0(t, x, z) = P_H(t, x, z)$$

with effective square volatility $\langle f^2 \rangle Z_t = Z_t$,
and effective correlation $\rho \rightarrow \rho_{xz} \langle f \rangle$

More Formulas!

$$P_1(t, x, z) = \frac{e^{-r\tau}}{2\pi} \int e^{-ikq} \left(\kappa \theta \hat{f}_0(\tau, k) + z \hat{f}_1(\tau, k) \right) \\ \times \hat{G}(\tau, k, z) \hat{h}(k) dk,$$

$$\hat{f}_0(\tau, k) = \int_0^\tau \hat{f}_1(t, k) dt,$$

$$\hat{f}_1(\tau, k) = \int_0^\tau b(s, k) e^{A(\tau, k, s)} ds.$$

$$b(\tau, k) = - \left(V_1 D(\tau, k) (-k^2 + ik) + V_2 D^2(\tau, k) (-ik) \right. \\ \left. + V_3 (ik^3 + k^2) + V_4 D(\tau, k) (-k^2) \right).$$

- $A(\tau, k, s)$ solves ODE in τ

Goup Parameters: the V 's

- P_1 is linear function of four constants

$$V_1 = \rho_{yz} \sigma \nu \sqrt{2} \langle \phi' \rangle,$$

$$V_2 = \rho_{xz} \rho_{yz} \sigma^2 \nu \sqrt{2} \langle \psi' \rangle,$$

$$V_3 = \rho_{xy} \nu \sqrt{2} \langle f \phi' \rangle,$$

$$V_4 = \rho_{xy} \rho_{xz} \sigma \nu \sqrt{2} \langle f \psi' \rangle.$$

- $\psi(y)$ and $\phi(y)$ solve Poisson equations

$$\mathcal{L}_0 \phi = \frac{1}{2} (f^2 - \langle f^2 \rangle),$$

$$\mathcal{L}_0 \psi = f - \langle f \rangle.$$

- Each V_i has unique effect on implied volatility

Captures More Features of Smile

- Better fit for far ITM and OTM European options (SPX, $T=121$ days, on May 17, 2006)

Simultaneous Fit Across Expirations Is Improved

- Vast improvement for short expirations
- 65 days to maturity

Accuracy of Approximation: Smooth Payoffs Usual technique for smooth payoffs (Schwartz space of rapidly decaying functions):

- Write a PDE for the residual (model price minus next-order approximated price)
- Use probabilistic representation for parabolic PDEs with source (small of order ε) and terminal condition (small of order ε)
- Deduce residual is small of order ε

Well, not exactly because moments of Y_t need to be controlled uniformly in ε

Moments of Y

$$dY_t = \frac{Z_t}{\varepsilon}(m - Y_t)dt + \nu\sqrt{2}\sqrt{\frac{Z_t}{\varepsilon}}dW_t^y$$

$$Y_t = m + (y - m)e^{-\frac{1}{\varepsilon} \int_0^t Z_s ds} + \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}}e^{-\frac{1}{\varepsilon} \int_0^t Z_u du} \int_0^t e^{\frac{1}{\varepsilon} \int_0^s Z_u du} \nu\sqrt{Z_s} dW_s^y$$

We show that for any given $\alpha \in (1/2, 1)$ there is a constant C such that.

$$\mathbb{E}|Y_t| \leq C\varepsilon^{\alpha-1},$$

and therefore an accuracy of $\varepsilon^{1-\alpha}$

Numerical Illustration for Call Options Monte Carlo simulation for a European call option: standard Euler scheme, time step of 10^{-5} years, 10^6 sample paths with $\varepsilon = 10^{-3}$ so that $\sqrt{\varepsilon}V_3 = 0.0303$ is of the same order as V_3^ε , the largest of the V_i^ε 's obtained in the data calibration example. The parameters used in the simulation are:

$$\begin{aligned}x &= 100, z = 0.24, r = 0.05, \kappa = 1, \theta = 1, \sigma = 0.39, \rho_{xz} = -0.35, \\y &= 0.06, m = 0.06, \nu = 1, \rho_{xy} = -0.35, \rho_{yz} = 0.35, \\ \tau &= 1, K = 100,\end{aligned}$$

and $f(y) = e^{y-m-\nu^2}$ so that $\langle f^2 \rangle = 1$.

ε	$\sqrt{\varepsilon} P_1$	$P_0 + \sqrt{\varepsilon} P_1$	\hat{P}_{MC}	$\hat{\sigma}_{MC}$	$ P_0 + \sqrt{\varepsilon} P_1 - \hat{P}_{MC} $
0	0	21.0831	-	-	-
10^{-3}	-0.2229	20.8602	20.8595	0.0364	0.0007

Summary

- **Heston model** provides easy way to calculate option prices in stochastic volatility setting, but fails to capture some features of implied volatility surface
- **Multiscale model** offers improved fit to implied volatility surface while maintaining convenience of option pricing formulas

Present work with Matt Lorig to appear in the *SIAM Journal on Financial Mathematics*

Work in preparation for **Risk**: formulas for **fast and slow time scales** around Heston (Heston 2.0).
