Linear systems in (max,+) algebra

Max Plus
INRIA
Le Chesnay, France

Abstract

In this paper, we study the general system of linear equations in the (max, +) algebra. We introduce a symmetrization of this algebra and a new notion called balance which generalizes classical equations. This construction results in the linear closure of the (max, +) algebra in the sense that every non-degenerate system of linear balances has a unique solution given by Cramer’s rule.

1 Introduction

The (max, +) algebra plays a crucial role in at least two fields:

- path algebra (research of the path of maximal weight in a graph).

In this paper, we examine a fundamental problem in this algebra: solving systems of linear equations.

Let us start by introducing the notation used throughout this paper. We shall denote max by ⊕ (i.e. max(a, b) is noted a + b), and use ⊙ instead of the usual addition (e.g. 2 ⊙ 3 = 5), −∞ (also denoted by ε) is the null element for ⊕ (x ⊕ −∞ = x) and is absorbing for the product (−∞ ⊙ x = −∞). 0 is the unit element: 0 ⊙ x = x. (ℝ max {−∞}, ⊕, ⊙) is called the “(max, +) algebra”, or simply ℝ max. Usual computational rules hold in ℝ max (for instance a ⊙ (b ⊕ c) = (b ⊕ c) ⊙ a = (b ⊙ a) ⊕ (c ⊙ a)). This in particular allows us to define and manipulate vectors and matrices as usual. For simplicity, we sometimes omit ⊙ (we write ab instead of a ⊙ b).

A general account of this kind of algebraic structures can be found in Gondran and Minoux [7] for the graph theoretic point of view and Cohen, Moller, Quadrat and Viot [4] for the Discrete Event Systems point of view.

For more than thirty years, it has been known that the implicit vector equation \( x = \mathcal{A} \odot x \oplus b \) (\( \mathcal{A} \) being a \( n \times n \) matrix) can be solved by iteration, leading to the study of \( \mathcal{A}^* = \text{Id} \oplus \mathcal{A} \oplus \mathcal{A}^2 \oplus \ldots \). Other vector equations of the type \( H \otimes x = b \) (\( H \\ not being necessarily a square matrix) also can be dealt with by using residuation theory (see Blyth [1]). But for the most general system of \( n \) linear equations with \( n \) unknowns

\[
A \otimes x \oplus b = C \otimes x \oplus d
\]

where \( A \) and \( C \) are \( n \times n \) matrices with entries in \( \mathbb{R}_{\text{max}} \) and \( b,d \) are vectors of \( (\mathbb{R}_{\text{max}})^n \), no result existed until now to the best of the authors’ knowledge. In section 2, we first explain why the general equation (1) is essential for the study of Discrete Event Systems. Then, we embed the \((\text{max},+)\) algebra into a symmetrized algebra (cf. Section 3.2), where the balance relation \( \Delta \) plays the role of equality (Definition 3.1). The original elements are identified with positive elements in this new algebra. We associate the system of balances \((A \odot C) x = d \) with system (1). Among the many solutions balances may have, a restricted class can be associated with solutions in the \((\text{max},+)\) algebra: these are signed solutions (i.e. positive, negative, or null). The main result of this paper states that non-degenerate systems of linear balances always have a unique signed solution, given by Cramer’s rule (Theorem 6.1). When this solution is positive, it determines the unique solution of system (1).

Example 1.1

Find the solutions of:

\[
\begin{align*}
\text{max}(x, y - 4, 1) &= \text{max}(x - 1, y + 1, 2) \\
\text{max}(x + 3, y + 2, -5) &= \text{max}(y + 2, 7)
\end{align*}
\]

or in matrix form

\[
\begin{pmatrix}
0 & -4 \\
3 & 2
\end{pmatrix} \odot \begin{pmatrix}
x \\
y
\end{pmatrix} \oplus \begin{pmatrix}
1 \\
-5
\end{pmatrix} = \begin{pmatrix}
-1 & 1 \\
-\infty & 2
\end{pmatrix} \odot \begin{pmatrix}
x \\
y
\end{pmatrix} \oplus \begin{pmatrix}
2 \\
7
\end{pmatrix}.
\]

This problem is solved in Section 6.1. Before going into further details, let us make a simple remark: if \( a > b \), the equation \( a = x \oplus b \) is equivalent to \( a = x \). This suggests the naive rule: “\( a \oplus b = a \) if \( a > b \)”.

We can now try to “solve” system (2) using this naive rule:

\[
\begin{align*}
(2) & \Rightarrow \begin{cases}
(i) & x \oplus (-4)y \oplus 1 = (-1)x \oplus 1y \oplus 2 \\
(ii) & 3x \oplus 2y \oplus (-5) = 2y \oplus 7
\end{cases} \\
(3) & \Rightarrow [0 \oplus (-1)]x = [1 \oplus (-4)]y \oplus (2 \oplus 1) \\
& \Rightarrow (i') : x = 1y \oplus 2
\end{align*}
\]

We can solve it using residuation theory and checking that \( x, y \) is a solution of system (2).

Our goal is to make it clear when and why these calculations are valid.
To see why equations of type (1) are fundamental in the (max, +) algebra and its applications, we need to review some of the work done in developing a system theory in this algebra. In the context of DEDS, Cohen, Dubois, Moller, Quadrat and Viot (see [2, 4]) have developed a system theory, analogous to the conventional system theory for linear differential and recurrent equations. They have shown that a restricted class of the conventional system theory for linear differential and invertible matrices with entries in Vioit (see [2, 4]) have developed a system theory, analogous to the system theory in vector structures over the \( \mathbb{R}_{\text{max}} \) algebra. This class can be used to model flexible workshops, some distributed processing systems, and in particular systems involving synchronization constraints. A complete study, leading to the concepts of state-space representation and transfer function can be found in [4].

The study of general linear equations of type (1) appears to be the theoretical background needed to deal with the following interesting topics:

**Notions of rank** Many notions of rank and of linear dependence in vector structures over the (max, +) algebra can be found in the literature. The following is a conventional one.

**Definition 2.1** \( \{ u_i \} \in I \) is free if the canonical map \( \{ \lambda_i \} \in I \mapsto \bigoplus_{i \in I} \lambda_i u_i \) is one to one.

This condition is practically “never” fulfilled. The following notion of weak independence has been studied by Moller [9] and Wagneur [13].

**Definition 2.2** \( \{ u_i \} \in I \) is weakly independent iff no vector \( u_i \) is spanned by the others \( \{ u_j \} \neq i \).

Weak independence has some “pathological” features: for instance, there exists an infinite family weakly independent in \( \mathbb{R}^a_{\text{max}} \) (see Cuninghame Green [5]).

From the early work of Gondran and Minoux [6], there is a more appealing definition of linear dependence, bearing a strong resemblance with classical linear algebra:

**Definition 2.3** \( \{ u_i \} \in I \) is dependent iff there exists a partition \( I = J \cup K \) and a non-trivial family of scalars \( \{ \lambda_i \} \) such that \( \bigoplus_{j \in J} \lambda_j u_j = \bigoplus_{k \in K} \lambda_k u_k \).

We have: \( \{ u_i \} \) free \( \Rightarrow \) \( \{ u_i \} \) non-dependent \( \Rightarrow \) \( \{ u_i \} \) weakly independent. In the case of Definition 2.3, the column vector defined by \( \Lambda = (\lambda_i) \) is solution of an equation of the type \( U \Lambda = u^t \Lambda \) which is a homogeneous form of equation (1).

**Controllability, Observability** It is well known that the only invertible matrices with entries in \( \mathbb{R}_{\text{max}} \) can be written as \( M = DS \) where \( D \) is a diagonal matrix with invertible entries and \( S \) is a permutation matrix (see e.g. [5]). This means that endomorphisms of \( (\mathbb{R}_{\text{max}})^n \) “never” invertible. As a consequence, defining an effective notion of controllability or observability is far from being obvious and the only notions studied so far are structural (see [3]). A sharper theory should be based on the notion 2.3 of dependence.

**Minimality** Some attempts (cf. Olsder [10]) have already been made suggesting that minimal realizations may be related to “two-sided” ARMA models:

\[
Y(n) \oplus A_1^t Y(n-1) \oplus \ldots \oplus A_k^t Y(n-k) \oplus B_1^t U(n) \oplus \ldots \oplus B_k^t U(n-k) = A_1^t Y(n-1) \oplus \ldots \oplus A_k^t Y(n-k) \oplus B_1^t U(n) \oplus \ldots \oplus B_k^t U(n-k)
\]

which clearly have the form of equation (1).

### 3 Symmetrizing the \((\text{max}, +)\) algebra

A natural approach to our problem may have been to embed the \((\text{max}, +)\) algebra into a structure in which every non-trivial scalar linear equation has at least one solution. Indeed, solving \( a \oplus x = \varepsilon \) means symmetrizing \( a \). Because \( \text{max} \) is idempotent (i.e. \( a \oplus a = \text{max}(a, a) = a \)), the following remark shows how hopeless it is to adapt the classical symmetrization of monoids (e.g. the way we build \( \mathbb{Z} \) from \( \mathbb{N} \)) to the \( \mathbb{R}_{\text{max}} \) context:

**Proposition 3.1** Every idempotent group is reduced to the null element.

**Proof** Assume the group \((G, \oplus)\) is idempotent with null element \( \varepsilon \). Let \( b \) be the symmetric element of \( a \in G \). Then \( a = a \oplus \varepsilon = a \oplus (a \oplus b) = (a \oplus a) \oplus b = a \oplus b = \varepsilon. \)

#### 3.1 The algebra of pairs

Let us now consider the set of pairs \( \mathbb{R}_{\text{max}}^2 \) endowed with the natural dioid\(^1\) structure:

\[
(x', y') \oplus (y', y'') = (x' \oplus y, x'' \oplus y') \\
(x', y') \odot (y', y'') = (x' y' \oplus x'' y', x' y'' \oplus x'' y')
\]

with \( (\varepsilon, \varepsilon) \) as the null element and \( (0, \varepsilon) \) as the unit element.

Let \( x = (x', x'') \) and define the minus sign as \( \ominus x = (x'', x') \). The absolute value of \( x \) is denoted by \( |x| = x' + x'' \). The balance operator \((\cdot)^*\) is defined by \( x^* = x \oplus x = (|x|, |x|) \).

It is immediate to check that \( | \cdot | \) and \( ^* \) are dioid morphisms (respectively onto \( \mathbb{R}_{\text{max}} \) and the diagonal of \( \mathbb{R}_{\text{max}}^2 \)). In addition, we have the following properties:

\[
\begin{align*}
(i) & \quad a^* = (\ominus a)^* \\
(ii) & \quad \text{idempotence} \quad a^{**} = a^* \\
(iii) & \quad \text{absorption} \quad a b^* = (a b)^* \\
(iv) & \quad \text{involution} \quad \ominus (\ominus a) = a \\
(v) & \quad \text{additive morphism} \quad \ominus (a \oplus b) = (\ominus a) \oplus (\ominus b) \\
(vi) & \quad \text{sign rule} \quad \ominus (a \oplus b) = (\ominus a) \ominus b. \\
\end{align*}
\]

In particular \((v) \Rightarrow (vi)\) allow us to write as usual \( a \oplus (\ominus b) = a \ominus b. \)

\(^1\)Recall that a dioid is a set \( D \) together with two laws \( \oplus \) and \( \odot \) such that:

(i): \( (\mathcal{D}, \oplus) \) is associative, commutative, idempotent (i.e. \( \forall a \ a \oplus a = a \)), with null element \( \varepsilon \), (ii): \( (\mathcal{D}, \odot) \) is associative with unit element \( e \), (iii): product is distributive over addition and (iv): the null element is absorbing (\( \forall a \ a \ominus \varepsilon = \varepsilon = a \ominus \varepsilon \)).
3.2 Quotient structure

**Definition 3.1** [Balance relation] Let \( x = (x', x'') \) and \( y = (y', y'') \). We say that \( x \) balances \( y \) (denoted by \( x \Delta y \)) if and only if \( x' \oplus y'' = x'' \oplus y' \).

It is fundamental to notice that \( \Delta \) is not transitive. For instance, consider \( (0, 1) \Delta (1, 1), (1, 1) \Delta (1, 0) \) but \( (0, 1) \not\Delta (1, 0) \! \). Since \( \Delta \) cannot be an equivalence relation, there is no point to define the quotient structure of \( \mathbb{P}_{\text{max}}^2 \) by \( \Delta \) (opposed to the conventional algebra in which \( \mathbb{P}_{\text{max}}^2 / \Delta \simeq \mathbb{Z} \)). However, we can introduce a new relation \( \mathcal{R} \) on \( \mathbb{P}_{\text{max}}^2 \)

\[
(x', x'') \mathcal{R} (y', y'') \Leftrightarrow \begin{cases} 
  x' \neq x'', y' \neq y'' , \text{ and } x' \oplus y'' = x'' \oplus y' & \text{otherwise,} \\
  (x', x'') = (y', y'') & \text{otherwise.}
\end{cases}
\]

which is an equivalence relation, stronger than \( \Delta \). It is easy to check that \( \mathcal{R} \) is compatible with the structure laws of \( \mathbb{P}_{\text{max}}^2 \), with the balance relation \( \Delta \) and also with the \( \oplus , | | \) and \( * \) operators.

**Definition 3.2** We set \( S_{\text{max}} = \mathbb{P}_{\text{max}}^2 / \mathcal{R} \) and we call it the symmetrized algebra of \( \mathbb{P}_{\text{max}}^2 \).

We distinguish three kinds of equivalence classes:

\[
\begin{align*}
(t, -\infty) = \{ (t, x''); x'' < t \} & \quad \text{called positive} \\
(-\infty, t) = \{ (x', t); x' < t \} & \quad \text{called negative} \\
(t, t) = \{ (t, t) \} & \quad \text{called balanced.}
\end{align*}
\]

By associating \( (t, -\infty) \) with \( t \in \mathbb{P}_{\text{max}}^2 \), we can identify \( \mathbb{P}_{\text{max}}^2 \) with the subdioid of positive or null classes, \( \mathbb{P}_{\text{max}}^\oplus \). The set of negative or null classes (of the form \( \oplus x \) for \( x \in \mathbb{P}_{\text{max}}^2 \)) will be denoted by \( \mathbb{P}_{\text{max}}^\ominus \), the set of balanced classes (of the form \( x^* \)) by \( \mathbb{P}_{\text{max}}^* \). This yields the decomposition

\[
S_{\text{max}} = \mathbb{P}_{\text{max}}^\oplus \cup \mathbb{P}_{\text{max}}^\ominus \cup \mathbb{P}_{\text{max}}^*
\]

(5)

\( \varepsilon \) being the only element common to any two of these three sets. This should be compared with \( \mathbb{Z} = \mathbb{N}^+ \cup \mathbb{N}^- \).

These conventions allow us to write \( 3 \oplus 2 = 2 \) instead of \( [3, -\infty) \oplus \{ -\infty, 2 \} \). We thus have \( 3 \oplus 2 = \{ 3, 2 \} = \{ 3, -\infty \} = 3 \). More generally, calculations in \( S_{\text{max}} \) can be summarized as follows

\[
a \oplus b = a \quad \text{if } a > b \\
b \oplus a = a \quad \text{if } a > b \quad \text{absorbing.}
\]

(6)

This includes and generalizes the initial naive rule (3).

Because of its importance, we introduce the notation \( \mathbb{P}_{\text{max}}^\mid \) for the set \( \mathbb{P}_{\text{max}}^\oplus \cup \mathbb{P}_{\text{max}}^\ominus \). The elements of \( \mathbb{P}_{\text{max}}^\mid \) are called signed elements. They are either positive, negative or null. We have:

**Proposition 3.2** \( \mathbb{P}_{\text{max}}^\mid \setminus \{ \varepsilon \} = S_{\text{max}} \setminus \mathbb{P}_{\text{max}}^* \) is the set of all invertible elements of \( S_{\text{max}} \).

**Proof** \( t \ominus (-t) = (\ominus t) \oplus (\ominus -t) = 0 \) for \( t \in \mathbb{P}_{\text{max}}^\mid \setminus \{ \varepsilon \} \) obviously shows that every non-null element of \( \mathbb{P}_{\text{max}}^\mid \) is invertible. Moreover, formula (4,(iii)) shows that \( \mathbb{P}_{\text{max}}^* \) is absorbing for the product. Thus, \( x^* y \neq 0 \) for all \( y \in S_{\text{max}} \) since \( 0 \notin \mathbb{P}_{\text{max}}^\mid \).

**Remark 3.1** It can be proved that \( \mathcal{R} \) is the weakest equivalence relation stronger than \( \Delta \). In this sense \( \mathcal{R} \) is natural.

**Remark 3.2** There is a nicer algebraic way to introduce the relation \( \mathcal{R} \). Let \( \text{Sol}(a) = \{ x \in \mathbb{P}_{\text{max}}^\mid ; x \Delta a \} \), then it can easily be verified that

\[
x \mathcal{R} y \iff \text{Sol}(x) = \text{Sol}(y) \tag{7}
\]

which makes it clear that \( \mathcal{R} \) is an equivalence relation. This leads to a very simple proof of the compatibility of \( \mathcal{R} \) with addition. Because the following propositions are equivalent:

\[
x \in \text{Sol}(a \oplus c) \\
x \Delta a \oplus c \\
x \Delta c \Delta a \\
x \Delta c \in \text{Sol}(a)
\]

\( \text{Sol}(a) = \text{Sol}(b) \) implies that \( \text{Sol}(a \oplus c) = \text{Sol}(b \oplus c) \).

**Remark 3.3** The equivalent formulation (7) allows extending symmetrization to more general doids than the \( (\text{max}, +) \) algebra. In fact, it is always possible to define the quotient of the additive monoid of pairs by the map \( a \mapsto \text{Sol}(a) \), but this quotient may not be compatible with multiplication! What is specific to the total order structure of \( \mathbb{P}_{\text{max}}^\mid \) is the decomposition (5). Since our goal here is to give an existence and uniqueness theorem, we only consider the case of a totally ordered multiplicative group, the generic case of which being the \( (\text{max}, +) \) algebra. But a more general theory can be developed along the same lines.

4 Linear balances

4.1 General properties

Before solving general linear balances, we need to explain why balances in \( S_{\text{max}} \) generalize equations in \( \mathbb{P}_{\text{max}}^\mid \). The main algebraic features of balances are:

**Properties 4.1**

(i) \( a \Delta a \) (reflexivity)

(ii) \( a \Delta b \iff b \Delta a \) (symmetry)

(iii) \( a \Delta b \iff a \ominus b \Delta \varepsilon \) (transitivity)

(iv) \( a \Delta b, c \Delta d \Rightarrow a \oplus c \Delta a \oplus b \oplus d \) (absorbing)

(v) \( a \Delta b \Rightarrow ac \Delta bc \) (absorbing)

Let us prove (v): \( a \Delta b \Rightarrow a \ominus b \in \mathbb{P}_{\text{max}}^\mid \) and as \( \mathbb{P}_{\text{max}}^* \) is absorbing, \( (a \ominus b)c = ac \ominus bc \in \mathbb{P}_{\text{max}}^\mid \), i.e. \( ac \Delta bc \).

Although \( \Delta \) is not transitive, when some variables are signed, we can manipulate balances in the same way as we manipulate equations:

**Property 4.2** [Weak substitution]

\[
\begin{align*}
\text{let } x \Delta a \\
\text{and } x \in \mathbb{P}_{\text{max}}^\mid \Rightarrow cx \Delta b.
\end{align*}
\]

**Proof** We have \( x \in \mathbb{P}_{\text{max}}^\mid \) or \( x \in \mathbb{P}_{\text{max}}^- \). Assume for instance that \( x \in \mathbb{P}_{\text{max}}^- \); \( x = (x', x^*) \). With obvious notations:

\[
x^* y \neq 0 \quad \text{for all } y \in S_{\text{max}} \text{ since } 0 \notin \mathbb{P}_{\text{max}}^*.
\]

By taking \( c = 0 \), the weak substitution property 4.2 becomes:
Property 4.3 [Weak transitivity]
\[ a \Delta x, \ x \Delta b \quad \text{and} \quad x \in \mathbb{R}_{\text{max}}^\vee \Rightarrow a \Delta b \]
We conclude by a simple remark which allows translating balances into equalities:

Property 4.4 [Reduction of balances]
\[ x \Delta y \quad \text{and} \quad (x, y) \in (\mathbb{R}_{\text{max}}^\vee)^2 \Rightarrow x = y \]
It is immediate to extend balances to the vector case. Properties (4.1, i−v), 4.2, 4.3 and 4.4 still hold when \( a, b, x, y \) and \( c \) are matrices with appropriate dimensions, provided we replace “\( \in \mathbb{R}_{\text{max}}^\vee \)” by “every entry \( \in \mathbb{R}_{\text{max}}^\vee \)”. Therefore, we say a vector is signed iff every entry is signed.

4.2 From equations to balances
We now consider a solution \( x \) of the equation (1) in \( \mathbb{R}_{\text{max}} \). We have
\[ A x \oplus b \Delta C x \oplus d \quad (\text{reflexivity}), \quad \text{and} \quad (4.1, iii): \]
\[ (A \ominus C)x \oplus (b \ominus d) \quad \Delta \varepsilon . \quad (8) \]
Conversely, assuming that \( x \) is a positive solution of (8), we get
\[ A x \oplus b \Delta C x \oplus d \quad \text{with} \quad A \oplus b \text{ and } C x \oplus d \in \mathbb{R}_{\text{max}}^\vee \subset \mathbb{R}_{\text{max}}^\vee \]
Using 4.4, we get \( A x \oplus b = C x \oplus d \). So, we have:

Proposition 4.5 The set of solutions of the general linear system of equations (1) in \( \mathbb{R}_{\text{max}}^\vee \) and the set of positive solutions of the associated linear balance (8) in \( \mathbb{S}_{\text{max}} \) coincide.

Thus, the original problem reduces to studying linear balances in \( \mathbb{S}_{\text{max}} \).

Remark 4.1 The case where a solution \( x \) of (8) has some negative and some positive entries is also of interest. We write \( x = x^+ \ominus x^- \quad \text{with} \quad x^+, x^- \in (\mathbb{R}_{\text{max}}^\vee)^n \). Partitioning the columns of \( A \) and \( C \) according to the sign of the entries of \( x \): \( A = A^+ \oplus A^-; C = C^+ \oplus C^- \) (in such a way that \( A x = A^+ x^+ \ominus A^- x^- \) and \( C x = C^+ x^+ \ominus C^- x^- \)), we can affirm the existence of a solution to the new problem
\[ A^+ x^+ \ominus C^- x^- \oplus b = A^- x^- \ominus C^+ x^+ \oplus d . \]

4.3 The scalar linear balance
Theorem 4.6 Let \( a \in \mathbb{R}_{\text{max}}^\vee \setminus \{e\} \) and \( b \in \mathbb{R}_{\text{max}}^\vee \), then the balance
\[ a x \oplus b \Delta \varepsilon \]
has the unique signed solution: \( x^\dagger = \ominus a^{-1} b \)

Proof From properties 4.1, 1 and 4.1, iii, \( a x \oplus b \Delta \varepsilon \) is equivalent to \( x \Delta \ominus a^{-1} b \). Using the reduction property 4.4 and \( \ominus a^{-1} b \in \mathbb{R}_{\text{max}}^\vee \), we get \( x = \ominus a^{-1} b \).

Remark 4.2 Non-trivial linear balances always have solutions in \( \mathbb{S}_{\text{max}} \), that is why \( \mathbb{S}_{\text{max}} \) may be considered as a linear closure of \( \mathbb{R}_{\text{max}} \).

Remark 4.3 We can describe all the solutions of (9). For all \( t \in \mathbb{R}_{\text{max}} \), we have obviously \( a t^\dagger \Delta \varepsilon \). Adding this balance to \( a x^\dagger \oplus b \Delta \varepsilon \), we get \( a (x^\dagger + t^\dagger) \oplus b \Delta \varepsilon \). Thus,
\[ x_t = x^\dagger + t^\dagger \quad (10) \]
is solution of (9). If \( t \geq |x^\dagger| \), then \( x_t = t^\dagger \) is balanced. Conversely, it can be checked that every solution of (9) may be written as in (10). The unique signed solution \( x^\dagger \) is also the least solution.

Remark 4.4 If \( b \not\in \mathbb{R}_{\text{max}}^\vee \), we lose uniqueness of signed solutions. Every \( x \) such that \( \|x\| \leq |b| \) (i.e., \( |x| \leq |a^{-1} b| \)) is solution of balance (9).

Remark 4.5 If \( a \not\in \mathbb{R}_{\text{max}}^\vee \), we again lose uniqueness. Assume \( b \in \mathbb{R}_{\text{max}}^\vee \) (otherwise, the balance holds for all value of \( x \)), then every \( x \) such that \( |a x| \geq |b| \) is a solution.

5 A fundamental identity
Before dealing with general systems, we need to extend the determinant machinery to the \( \mathbb{S}_{\text{max}} \) context. We define the sign of a permutation \( \sigma \) by \( \text{sgn}(\sigma) = 0 \) if \( \sigma \) is even and \( \text{sgn}(\sigma) = 0 \) if \( \sigma \) is odd. Then the determinant of an \( n \times n \) matrix \( A = (a_{ij}) \) is given (as usual) by
\[ \det A = \bigoplus_{\sigma} \text{sgn}(\sigma) \prod_{i=1}^{n} a_{i, \sigma(i)} . \]
det remains an \( n \)-linear antisymmetric function of the rows (or columns). \( \det A \) is balanced (but non-null in general) if two rows (or columns) of the matrix \( A \) are identical. We denote by \( A^{\text{adj}} \) the transpose of the matrix of cofactors \( (A^{\text{adj}})_{i,j} = \text{cof}_{ij}(A) \), and by \( I \) the identity matrix (with 0 on the diagonal and \( \varepsilon \) elsewhere). The following is just a “combinatorial” identity, that can be shown by adapting a result by Reutenauer & Straubing [12] or the usual demonstration:

Theorem 5.1 \( A A^{\text{adj}} \Delta \varepsilon = \det A \cdot I \).

Remark 5.1 The formulation of Reutenauer and Straubing consists in defining a “positive determinant” \( \det^+ A \) (where the sum is taken over all even permutations) and a “negative” determinant \( \det^- A \) (odd permutations). The matrix of “positive” cofactors is defined by
\[ [A^{\text{adj}^+}]_{i,j} = \begin{cases} \det^+ A(j|i) & \text{if } i + j \text{ even} \\ \det^- A(j|i) & \text{if } i + j \text{ odd} \end{cases} \]
where \( A(i|j) \) denotes the matrix \( A \) from which row \( i \) and column \( j \) are removed, and the matrix of “negative” cofactors \( A^{\text{adj}^-} \) is defined similarly. With these notations, Theorem 5.1 can be rewritten as follows:
\[ A A^{\text{adj}^+} \oplus \det^- A \cdot I = A A^{\text{adj}^-} \oplus \det^+ A \cdot I . \]
This formula does not use the \( \ominus \) sign and is valid in any semi-ring. The symmetrized algebra appears as a natural way of handling (and proving in an algebraic way) such identities.

6 Solving systems of linear balances

6.1 Cramer’s rule
Because of the remarks of section 4, we only consider the solutions of balances in \( (\mathbb{R}_{\text{max}}^\vee)^n \), that is signed solutions. We can now state the fundamental result for the existence and uniqueness of signed solutions of linear systems:
Theorem 6.1 (Cramer system) Let $A$ be an $n \times n$ matrix with entries in $S_{\max}$ and $b \in (S_{\max})^n$. Then every signed solution of
\[ Ax \Delta b \] satisfies:
\[ \det A \cdot x \Delta A^{adj}b. \] Conversely, assume that $A^{adj}b$ is signed and $det A$ is invertible, then the “Cramer solution” $x^* = (det A)^{-1} A^{adj}b$ is the unique signed solution of (11).

Proof Assume $det A$ is invertible and $A^{adj}b$ is signed. By right-multiplying the identity $AA^{adj} \Delta$ det $A$ Id by $(det A)^{-1} b$ we easily see that the Cramer signed solution $x^*$ satisfies (11). This proves the converse implication. We shall consider the direct implication only when $det A$ is invertible. The proof is by induction on the size of the matrix. Let us prove (12) for the last row, i.e. $det A_{n \times n} \Delta (A^{adj}b)_n$. Developing with respect to the last column, $det A = \sum_{k=1}^n a_{k,n} \det k,n(A)$ we get that at least one term is invertible, say $a_{1,n} \det 1,n(A)$. We now partition in an obvious way $A$ and $b$:
\[
A = \begin{bmatrix} a_{1,1} & a_{1,n} \\ A' & A_{n,n} \end{bmatrix}, \quad b = \begin{bmatrix} b_1 \\ b_n \end{bmatrix}, \quad x = \begin{bmatrix} x' \\ x_n \end{bmatrix}
\]
where $A_{1,1}$ is a $(n-1) \times (n-1)$ matrix, $A'$ is an $(n-1) \times (n-1)$ matrix, etc...
\[ Ax \Delta b \iff \begin{cases} A_{1,1} x' + a_{1,n} x_n \Delta b_1 & (\alpha) \\ A' x' + A_{n,n} x_n \Delta b' & (\beta) \end{cases} \]
Since $det A' = (e0)^{n-1} \det 1,n(A)$ is invertible, we apply the induction hypothesis to
\[ (\beta) \iff (\beta') : A' x' \Delta b' \Theta A_{n,n} x_n \]
which implies that $x' \Delta (det A')^{-1} A'^{adj} b' \Theta A_{n,n} x_n$. Using the weak substitution property 4.2, we replace $x' \in (S_{\max})^{n-1}$ in $(\alpha)$:
\[ A_{1,1} (det A')^{-1} A'^{adj} b' \Theta A_{n,n} x_n \]
i.e.
\[ \det A' a_{1,n} \Theta A_{1,1} A'^{adj} A_{n,n} x_n \Delta b_1 \]
\[ \det A' b_1 \Theta A_{1,1} A'^{adj} b' \]
Here, we recognize the developments of $(e0)^{n+1} \det A$ and $(e0)^{n+1} (A^{adj}b)_n$. Thus
\[ det A \cdot x_n \Delta (A^{adj}b)_n. \]
Since the same result holds when developing with respect to any column $k$ other than $n$, this concludes the proof.

Remark 6.1 Let $D_{x_i}$ be the determinant of the matrix obtained by replacing the $i$-th column of $A$ with $b$, then $(A^{adj}b)_i = D_{x_i}$. Assume $det A$ invertible, then the equation (12) is equivalent to:
\[ (\forall i) \quad x_i \Delta (det A)^{-1} D_{x_i}. \]
If $A^{adj}b \in (S_{\max})^n$, then $x_i = (det A)^{-1} D_{x_i}$, which is exactly the classical $i$-th Cramer formula.

Example 6.1 Let us go back to our original problem (Example 1). The balance corresponding to equation (2) is
\[
\begin{bmatrix} 0 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \Delta \begin{bmatrix} 2 \\ 7 \end{bmatrix}
\]
with determinant $D = 4$ (invertible).
\[ D_x = \begin{bmatrix} 2 & 1 \\ 7 & 2 \end{bmatrix} = 8, \quad D_y = \begin{bmatrix} 0 & 2 \\ 3 & 7 \end{bmatrix} = 7 \]
\[ A^{adj}b = \begin{bmatrix} D_x \\ D_y \end{bmatrix} = \begin{bmatrix} 8 \\ 7 \end{bmatrix} \in (S_{\max})^2. \]
So, $x = D_x / D_y = 8 - 4 = 4, y = D_y / D_x = 7 - 4 = 3$ gives the unique positive solution in $S_{\max}$ of balance (13). Thus, it is the unique solution of equation (2) in $S_{\max}$.

Example 6.2 In the two dimensional case, the condition $A^{adj}b \in (S_{\max})^n$ has a very clear geometric interpretation. The following picture represents the solutions to balances in the plane of signed coordinates $(S_{\max})^2$.

From Theorem 6.1, we easily see that the two lines $L_1$ and $L_2$ meet at a single point: $(1,1)$. However, $L_2$, which is “parallel” to $L_1$ has a degenerate intersection with $L_1$ because the second Cramer determinant of system $L_1, L_2$ is balanced.

Remark 6.2 det $A$ being invertible is not a necessary condition for system $Ax \Delta b$ to have a signed solution for all values of $b$! Consider
\[ A = \begin{bmatrix} 0 & 0 & \varepsilon \\ 0 & 0 & \varepsilon \\ 0 & 0 & \varepsilon \end{bmatrix} \]
det $A = \varepsilon$. Let $t \in S_{\max}^n$ such that $|b_i| \leq |t|$ for all coordinate $i$, and let $x = \begin{bmatrix} t \\ \varepsilon \end{bmatrix}$. Then $Ax \Delta b$.

Remark 6.3 As already noticed by Gondran and Minoux (see [6]), determinants have a natural interpretation in terms of assignment problems. So the Cramer computations have the same complexity as $n + 1$ assignment problems, which can be solved using flow algorithms.

6.2 General case

We can even solve $Ax \Delta b$ in some degenerate cases:

Theorem 6.2 Assume that det $A \neq \varepsilon$ (but possibly det $A \Delta \varepsilon$) then for all values of $b$ there exists a signed solution $x$ of $Ax \Delta b$ such that $|x| = |det A|^{-1} |A^{adj}b|$.

It is remarkable that the classical Gauss-Seidel and Jacobi algorithms can be adapted to the $S_{\max}$ case, for which we have convergence after $n$ iterations (!). This in particular provides an algorithmic proof of Theorem 6.2. We write $A = D \oplus U \ominus L$, with $U$ upper-triangular, $L$ lower-triangular and $D$ diagonal. Let us introduce the notation “$x \Delta y$” for $x \Delta y$ and $|x| = |y|$.

We now state:
Theorem 6.3 [Jacobi algorithm] Assume the domination property \( |\det A| = \prod_{i=1}^{n} a_{i|i} \neq \varepsilon \) then:
1/ There exists a (perhaps non-unique) sequence of signed vectors \( \{x^p\} \) such that
   (i) \( \varepsilon = x^0 \leq x^1 \leq \ldots \leq x^p \leq \ldots \)
   (ii) \( Dx^{p+1} + A \) \( \ominus (U \oplus L)x^p + b \).
2/ Such a sequence is stationary after \( n \) iterations \( (x^n = x^{n+1} = \ldots) \) and \( x^n \) is a solution of \( Ax + \Delta \varepsilon \).

\[ |A|^{-1} |A^w| = 0 \quad 1 \quad 2 \]

\[
\begin{bmatrix}
5 & 0 & 3 \\
1 & 3 & \ominus 1 \\
3 & \ominus 2 & 4 \\
\end{bmatrix}
\begin{bmatrix}
\begin{array}{c}
5
x_1 \\
3 x_2 \\
3 x_3
\end{array}
\end{bmatrix}
\Delta
\begin{bmatrix}
\begin{array}{c}
\ominus 1 \\
4 \\
0
\end{array}
\end{bmatrix}
\]

Sketch of proof 1/ can be shown by an induction argument which is omitted due to the lack of space. To understand why \( x^p \) is stationary, we introduce \( x^{p+1} \).

Lemma 6.4 \( (|D|^{-1} |U \oplus L|)^* |D|^{-1} = |\det A|^{-1} |A^w| \).

This can be deduced from a theorem due to Yoeli ([14], Theorem 4).

Example 6.3 We apply the Jacobi algorithm to

\[
\begin{bmatrix}
5 & 0 & 3 \\
1 & 3 & \ominus 1 \\
3 & \ominus 2 & 4 \\
\end{bmatrix}
\begin{bmatrix}
\begin{array}{c}
5
x_1 \\
3 x_2 \\
3 x_3
\end{array}
\end{bmatrix}
\Delta
\begin{bmatrix}
\begin{array}{c}
\ominus 1 \\
4 \\
0
\end{array}
\end{bmatrix}
\]

with \( |\det A|^{-1} |A^w| = 0 \quad 1 \quad 2 \).

\[
\begin{align*}
5 x_1 & \ominus 1 \\
3 x_2 & \ominus 1 \\
3 x_3 & \ominus 5
\end{align*}
\]

Different choices for \( x_1^2 \) and \( x_3^2 \) yield another solution: \( x_1^2 = 2 \), \( x_2^2 = 1 \).

For the homogeneous system, the analogy with the classical situation is complete. The following result generalizes a theorem of Gondran and Minoux [6]:

Theorem 6.5 [Homogeneous case] Let \( A \) be an \( n \times n \) matrix with entries in \( \overline{\mathbb{R}}_{\text{max}} \). Then the equation \( Ax + \Delta \varepsilon \) has a signed non-null solution if and only if \( |\det A|^{-1} |A^w| \).
