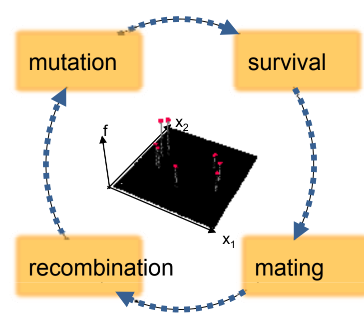
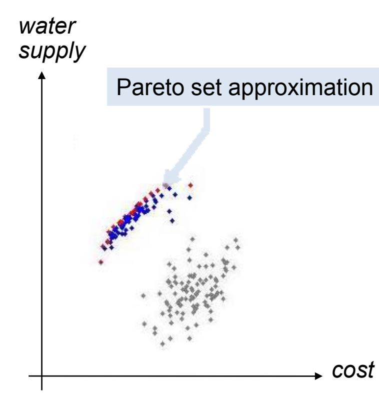
Evolutionary Multiobjective Optimization

Definition: EMO

EMO = **evolutionary algorithms** / randomized search algorithms

- applied to multiple criteria decision making (in general)
- used to approximate the Pareto-optimal set (mainly)

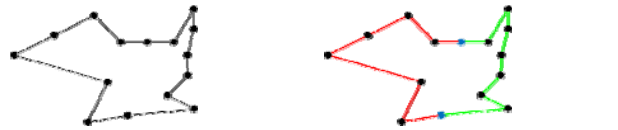




Multiobjectivization

Some problems are easier to solve in a multiobjective scenario

example: TSP
[Knowles et al. 2001]



$\pi \in S_n \rightarrow f(\pi)$ $\quad \pi \in S_n \rightarrow (f_1(\pi,a,b), f_2(\pi,a,b))$

Multiobjectivization

by addition of new “helper objectives” [Jensen 2004]

job-shop scheduling [Jensen 2004], frame structural design [Greiner et al. 2007], theoretical (runtime) analyses [Brockhoff et al. 2009]

by decomposition of the single objective

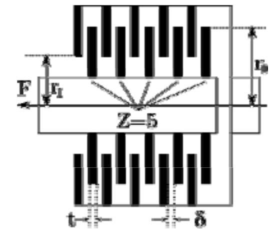
TSP [Knowles et al. 2001], minimum spanning trees [Neumann and Wegener 2006], protein structure prediction [Handl et al. 2008a], theoretical (runtime) analyses [Handl et al. 2008b]

Innovization

Often innovative design principles among solutions are found

example:
clutch brake design
[Deb and Srinivasan 2006]

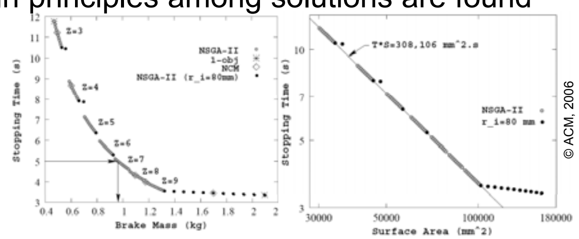
min. mass +
stopping time



Innovization

Often innovative design principles among solutions are found

example:
clutch brake design
[Deb and Srinivasan 2006]



Innovization [Deb and Srinivasan 2006]

= using machine learning techniques to find new and innovative design principles among solution sets

= learning about a multiobjective optimization problem

Other examples:

- SOM for supersonic wing design [Obayashi and Sasaki 2003]
- biclustering for processor design and KP [Ulrich et al. 2007]

The History of EMO At A Glance

1984 — first EMO approaches

dominance-based population ranking

1990 — dominance-based EMO algorithms with diversity preservation techniques

1995 — attainment functions

Overview

The Big Picture

Basic Principles of Multiobjective Optimization

- algorithm design principles and concepts
- performance assessment

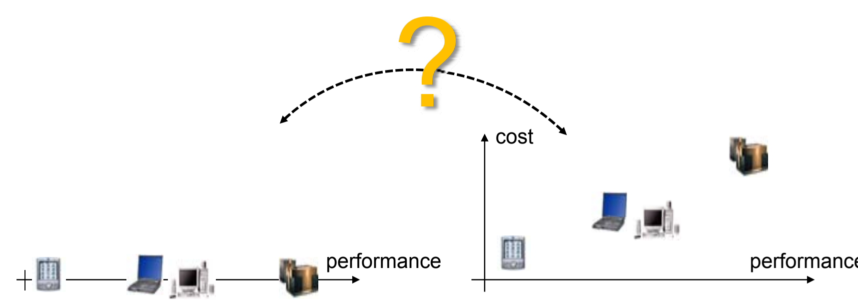
Selected Advanced Concepts

- indicator-based EMO
- preference articulation

A Few Examples From Practice

Starting Point

What makes evolutionary multiobjective optimization different from single-objective optimization?



single objective **multiple objectives**

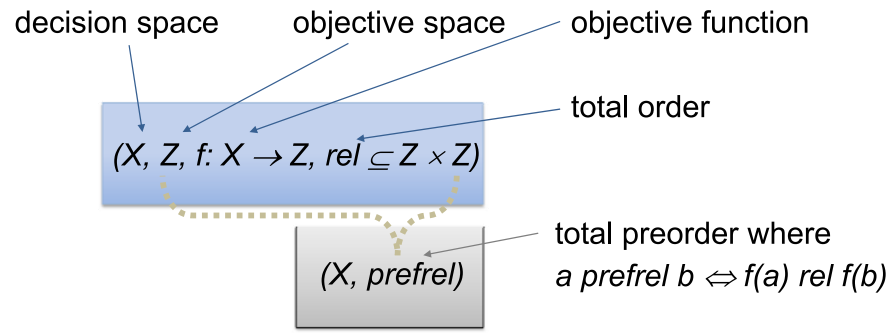
A General (Multiobjective) Optimization

A *multiobjective optimization problem* is defined by a 5-tuple $(X, Z, \mathbf{f}, \mathbf{g}, \leqslant)$ where

- X is the decision space,
- $Z = \mathbb{R}^n$ is the objective space,
- $\mathbf{f} = (f_1, \ldots, f_n)$ is a vector-valued function consisting of n objective functions $f_i : X \mapsto \mathbb{R}$,
- $\mathbf{g} = (g_1, \ldots, g_m)$ is a vector-valued function consisting of m constraint functions $g_i : X \mapsto \mathbb{R}$, and
- $\leqslant \subseteq Z \times Z$ is a binary relation on the objective space.

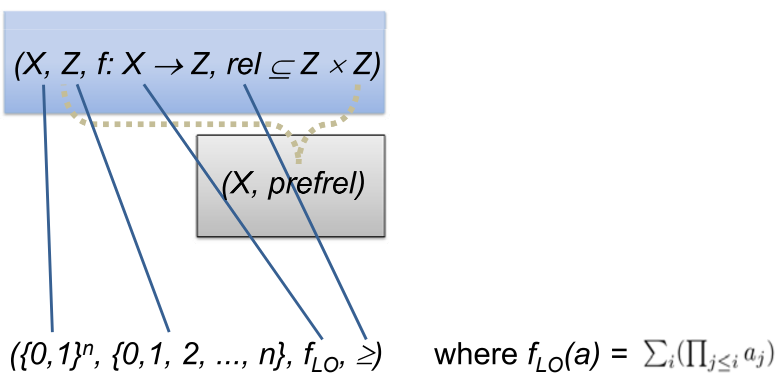
The goal is to identify a decision vector $\mathbf{a} \in X$ such that (i) for all $1 \leq i \leq m$ holds $g_i(\mathbf{a}) \leq 0$ and (ii) for all $\mathbf{b} \in X$ holds $\mathbf{f}(\mathbf{b}) \leqslant \mathbf{f}(\mathbf{a}) \Rightarrow \mathbf{f}(\mathbf{a}) \leqslant \mathbf{f}(\mathbf{b})$.

A Single-Objective Optimization Problem



A Single-Objective Optimization Problem

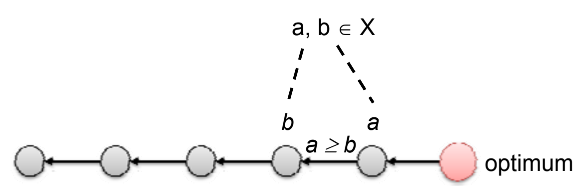
Example: Leading Ones Problem



where $f_{LO}(a) = \sum_i (\prod_{j \leq i} a_j)$

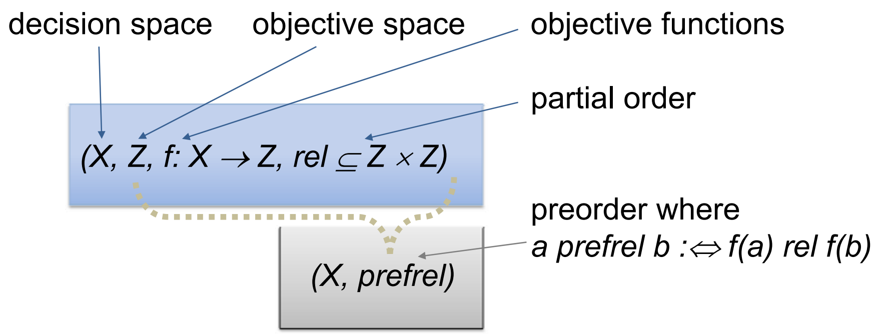
Simple Graphical Representation

Example: $\geq$ (total order)



totally ordered

Preference Relations



$$(X, \preccurlyeq_{par})$$

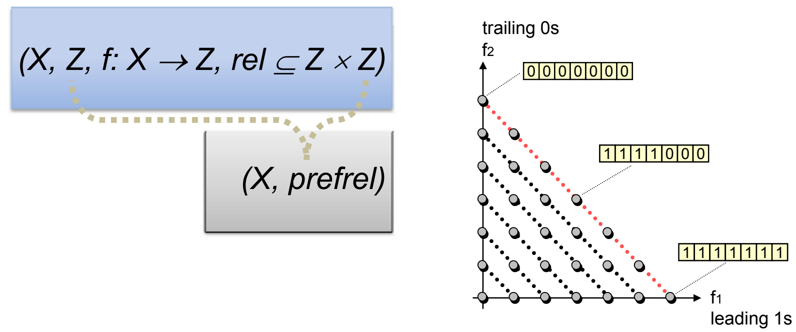
$$\downarrow$$

$$a \preccurlyeq_{par} b :\Leftrightarrow f(a) \leqslant_{par} f(b)$$

weak Pareto dominance

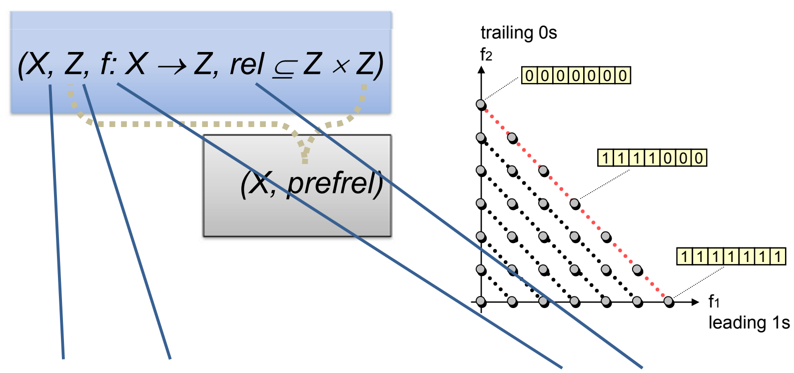
A Multiobjective Optimization Problem

Example: Leading Ones Trailing Zeros Problem



A Multiobjective Optimization Problem

Example: Leading Ones Trailing Zeros Problem



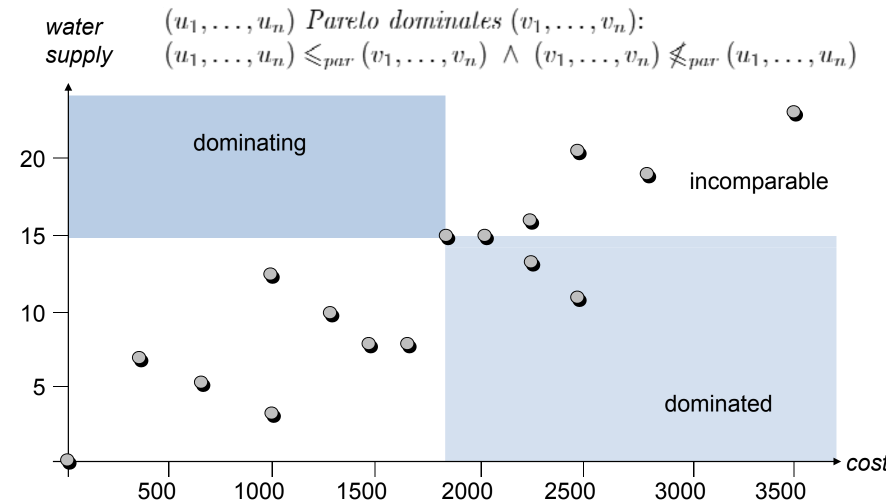
$(\{0,1\}^n, \{0,1, 2, ..., n\} \times \{0,1, 2, ..., n\}, (f_{LO}, f_{TZ}),$ **?** $)$

$f_{LO}(a) = \sum_i (\prod_{j \le i} a_j)$ $\quad f_{TZ}(a) = \sum_i (\prod_{j \le i} (1 - a_j))$

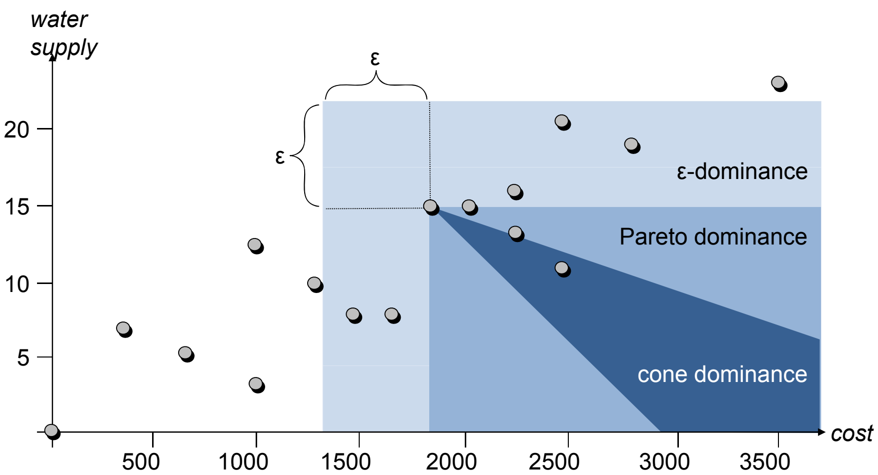
Pareto Dominance

$(u_1, \ldots, u_n)$ *weakly Pareto dominates* $(v_1, \ldots, v_n)$:
$(u_1, \ldots, u_n) \leqslant_{par} (v_1, \ldots, v_n) :\Leftrightarrow \forall 1 \le i \le n : u_i \le v_i$

$(u_1, \ldots, u_n)$ *Pareto dominates* $(v_1, \ldots, v_n)$:
$(u_1, \ldots, u_n) \leqslant_{par} (v_1, \ldots, v_n) \;\wedge\; (v_1, \ldots, v_n) \not\leqslant_{par} (u_1, \ldots, u_n)$



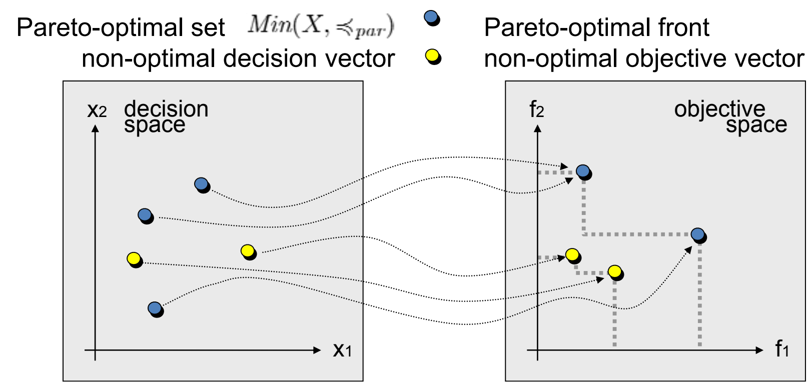
Different Notions of Dominance



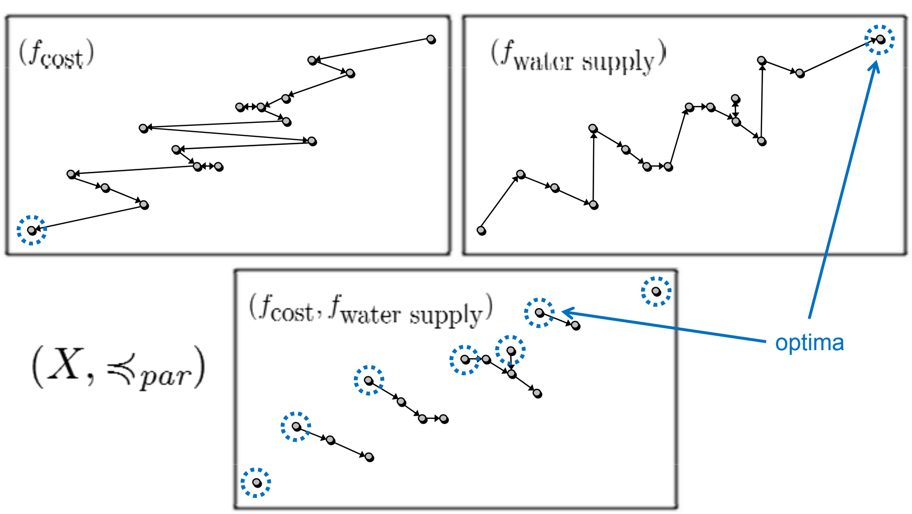
The Pareto-optimal Set

The *minimal set* of a preordered set $(Y, \leqq)$ is defined as

$$Min(Y, \leqq) := \{a \in Y \mid \forall b \in Y : b \leqq a \Rightarrow a \leqq b\}$$



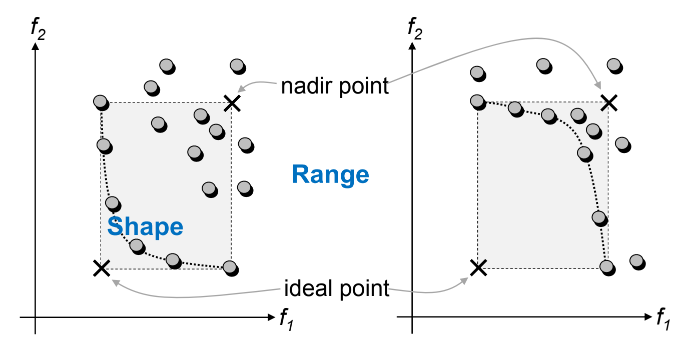
Visualizing Preference Relations



Remark: Properties of the Pareto Set

Computational complexity:
multiobjective variants can become NP- and #P-complete

Size: Pareto set can be exponential in the input length
(e.g. shortest path [Serafini 1986], MSP [Camerini et al. 1984])



Approaches To Multiobjective Optimization

A multiobjective problem is as such underspecified
…because not any Pareto-optimum is equally suited!

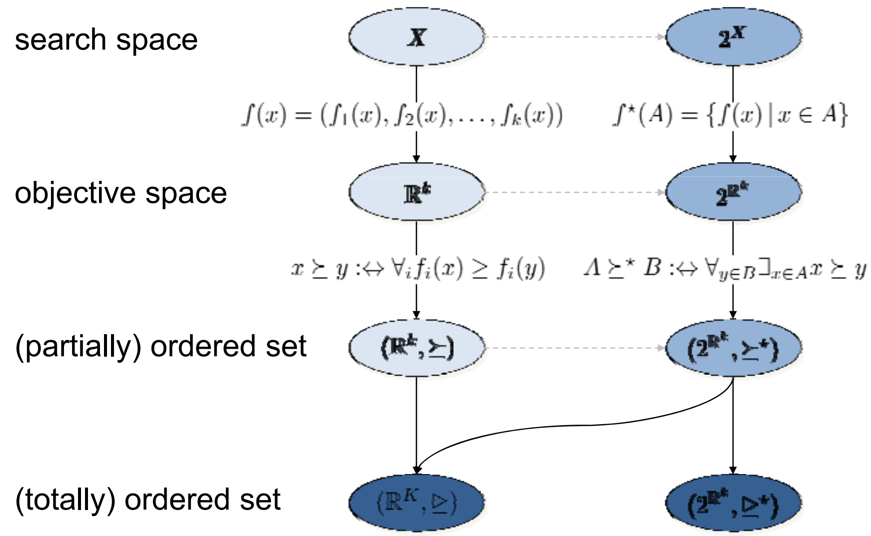
Additional preferences are needed to tackle the problem:

Solution-Oriented Problem Transformation:
Induce a total order on the decision space, e.g., by aggregation.

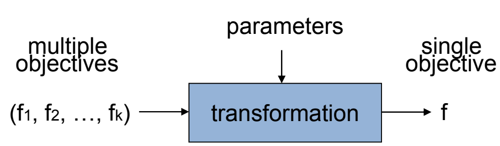
Set-Oriented Problem Transformation:
First transform problem into a set problem and then define an objective function on sets.

Preferences are needed in any case, but the latter are weaker!

Problem Transformations and Set Problems

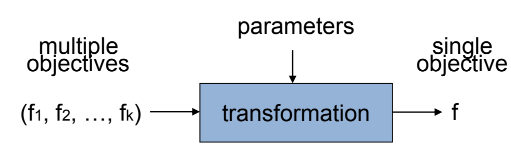


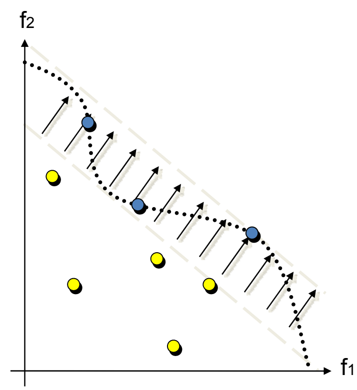
Solution-Oriented Problem Transformations



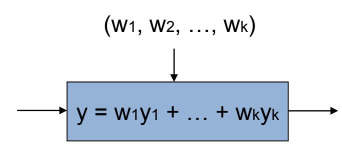
A *scalarizing function* s is a function $s : Z \mapsto \mathbb{R}$ that maps each objective vector $(u_1, \ldots, u_n) \in Z$ to a real value $s(u_1, \ldots, u_n) \in \mathbb{R}$.

Aggregation-Based Approaches





Example: weighting approach



Other example: Tchebycheff
$y = \max w_i(u_i - z_i)$

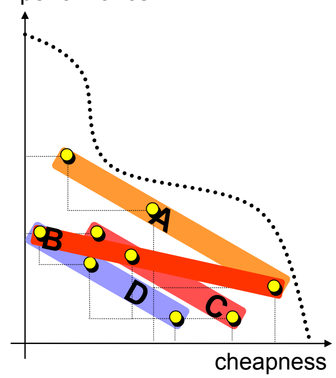
Set-Oriented Problem Transformations

For a multiobjective optimization problem $(X, Z, \mathbf{f}, \mathbf{g}, \leqslant)$, the associated *set problem* is given by $(\Psi, \Omega, F, \mathbf{G}, \preccurlyeq)$ where

- $\Psi = 2^X$ is the space of decision vector sets, i.e., the powerset of X,
- $\Omega = 2^Z$ is the space of objective vector sets, i.e., the powerset of Z,
- F is the extension of $\mathbf{f}$ to sets, i.e., $F(A) := \{\mathbf{f}(\mathbf{a}) \,:\, \mathbf{a} \in A\}$ for $A \in \Psi$,
- $\mathbf{G} = (G_1, \ldots, G_m)$ is the extension of $\mathbf{g}$ to sets, i.e., $G_i(A) := \max\{g_i(\mathbf{a}) \,:\, \mathbf{a} \in A\}$ for $1 \leq i \leq m$ and $A \in \Psi$,
- $\preccurlyeq$ extends $\leqslant$ to sets where $A \preccurlyeq B :\Leftrightarrow \forall \mathbf{b} \in B\ \exists \mathbf{a} \in A : \mathbf{a} \leqslant \mathbf{b}$.

Pareto Set Approximations

Pareto set approximation (algorithm outcome) = set of (usually incomparable) solutions



A weakly dominates **B**
= not worse in all objectives and sets not equal

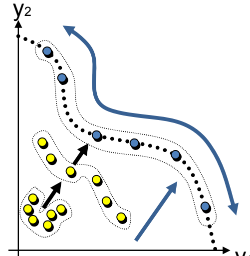
C dominates **D**
= better in at least one objective

A strictly dominates **C**
= better in all objectives

B is incomparable to **C**
= neither set weakly better

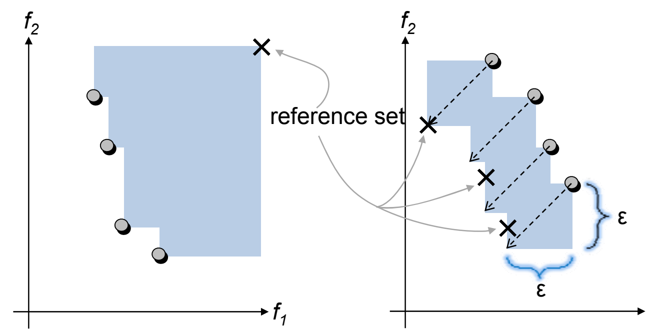
What Is the Optimization Goal (Total Order)?

- Find all Pareto-optimal solutions?
  - Impossible in continuous search spaces
  - How should the decision maker handle 10000 solutions?
- Find a representative subset of the Pareto set?
  - Many problems are NP-hard
  - What does representative actually mean?
- Find a good approximation of the Pareto set?
  - What is a good approximation?
  - How to formalize intuitive understanding:
    ❶ close to the Pareto front
    ❷ well distributed



Quality of Pareto Set Approximations

A (unary) *quality indicator* I is a function $I : \Psi \mapsto \mathbb{R}$ that assigns a Pareto set approximation a real value.



hypervolume indicator epsilon indicator

General Remarks on Problem

Idea:

Transform a preorder into a total preorder

Methods:

- Define single-objective function based on the multiple criteria *(shown on the previous slides)*
- Define any total preorder using a relation *(not discussed before)*

Question:

Is any total preorder ok resp. are there any requirements concerning the resulting preference relation?

$\Rightarrow$ Underlying dominance relation *rel* should be reflected

Refinements and Weak Refinements

❶ $\overset{ref}{\preccurlyeq}$ **refines** a preference relation $\preccurlyeq$ iff

$$A \preccurlyeq B \wedge B \not\preccurlyeq A \Rightarrow A \overset{ref}{\preccurlyeq} B \wedge B \overset{ref}{\not\preccurlyeq} A \qquad \textit{(better} \Rightarrow \textit{better)}$$

$\Rightarrow$ fulfills requirement

❷ $\overset{ref}{\preccurlyeq}$ **weakly refines** a preference relation $\preccurlyeq$ iff

$$A \preccurlyeq B \wedge B \not\preccurlyeq A \Rightarrow A \overset{ref}{\preccurlyeq} B \qquad \textit{(better} \Rightarrow \textit{weakly better)}$$

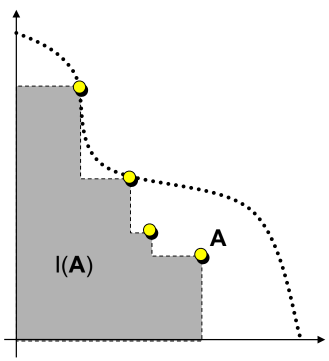
$\Rightarrow$ does not fulfill requirement, but $\overset{ref}{\preccurlyeq}$ does not contradict $\preccurlyeq$

…sought are total refinements…

Example: Refinements Using Indicators

$A \overset{ref}{\preccurlyeq} B :\Leftrightarrow I(A) \geq I(B)$

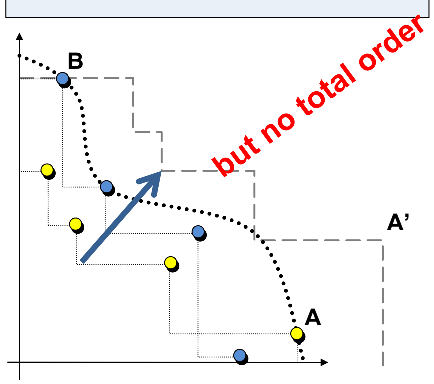
I(A) = volume of the weakly dominated area in objective space



unary hypervolume indicator

$A \overset{ref}{\preccurlyeq} B :\Leftrightarrow I(A,B) \leq I(B,A)$

I(A,B) = how much needs A to be moved to weakly dominate B

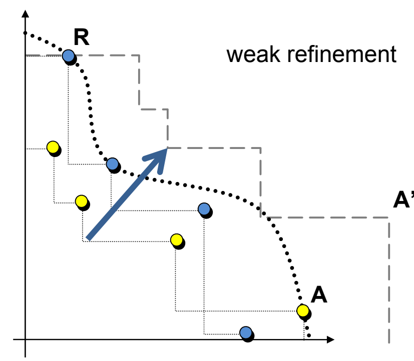


binary epsilon indicator

Example: Weak Refinement / No Refinement

$A \overset{ref}{\preccurlyeq} B :\Leftrightarrow I(A,R) \leq I(B,R)$

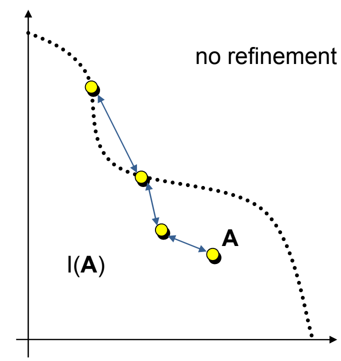
I(A,R) = how much needs A to be moved to weakly dominate R



unary epsilon indicator

$A \overset{ref}{\preccurlyeq} B :\Leftrightarrow I(A) \leq I(B)$

I(A) = variance of pairwise distances



unary diversity indicator

Overview

The Big Picture

Basic Principles of Multiobjective Optimization

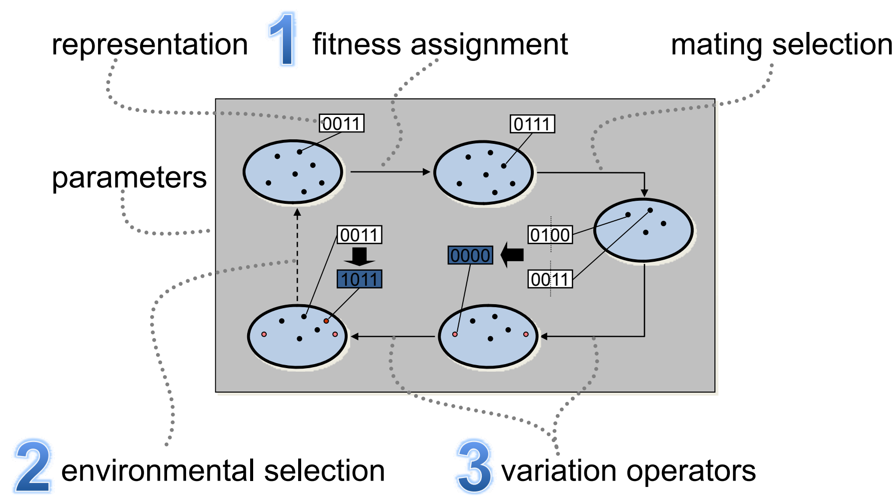
- algorithm design principles and concepts
- performance assessment

Selected Advanced Concepts

- indicator-based EMO
- preference articulation

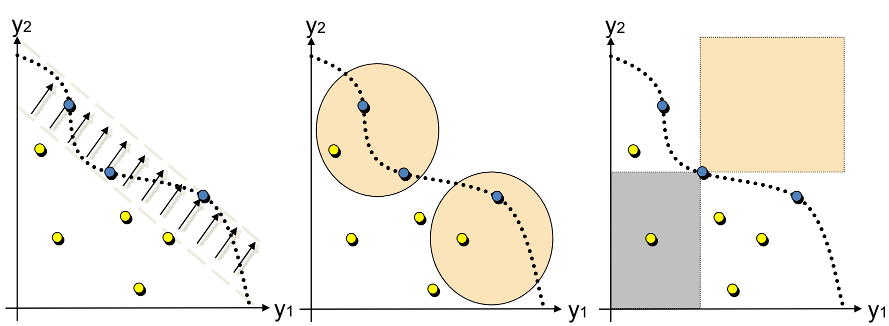
A Few Examples From Practice

Algorithm Design: Particular Aspects



Fitness Assignment: Principal Approaches

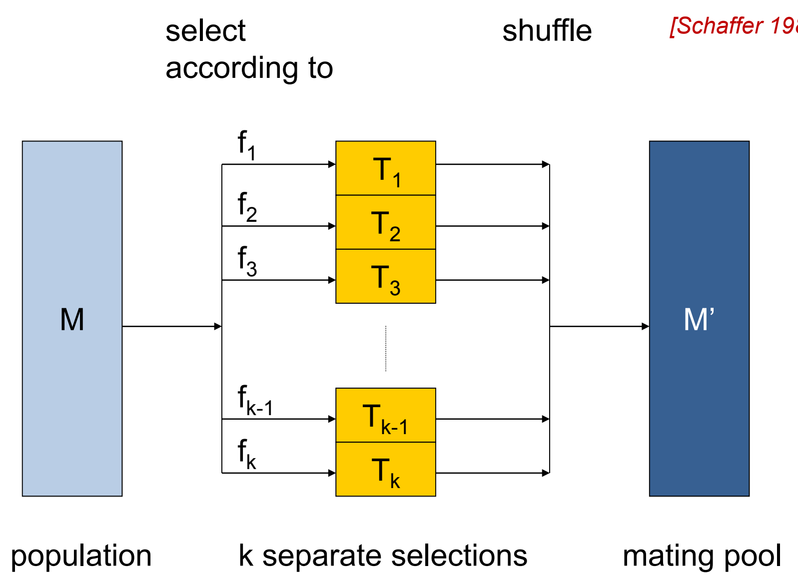
aggregation-based *weighted sum* | **criterion-based** *VEGA* | **dominance-based** *SPEA2*



parameter-oriented scaling-dependent ↔ set-oriented scaling-independent

Criterion-Based Selection: VEGA

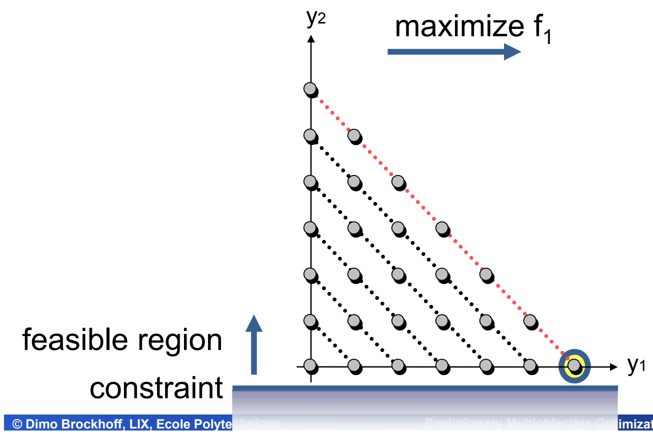
[Schaffer 1985]



Aggregation-Based: Multistart Constraint Method

Underlying concept:

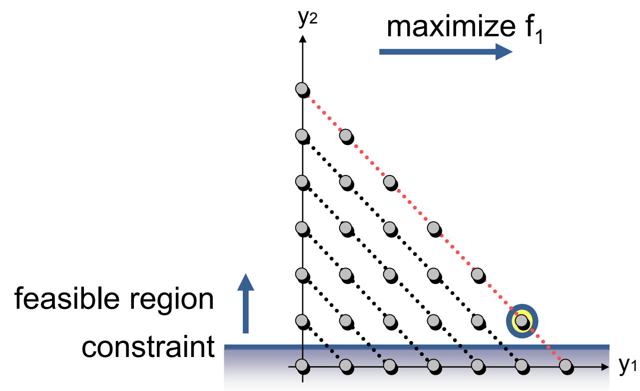
- Convert all objectives except of one into constraints
- Adaptively vary constraints



Aggregation-Based: Multistart Constraint Method

Underlying concept:

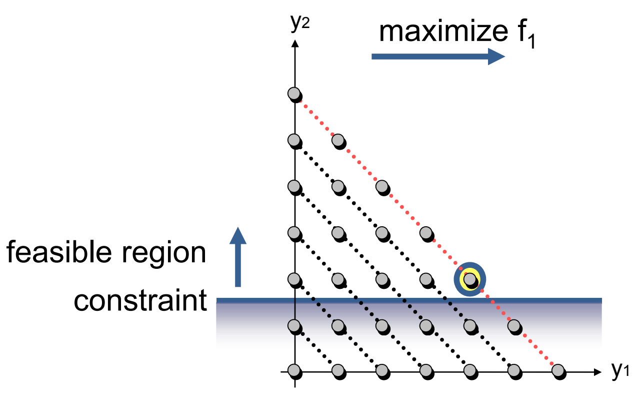
- Convert all objectives except of one into constraints
- Adaptively vary constraints



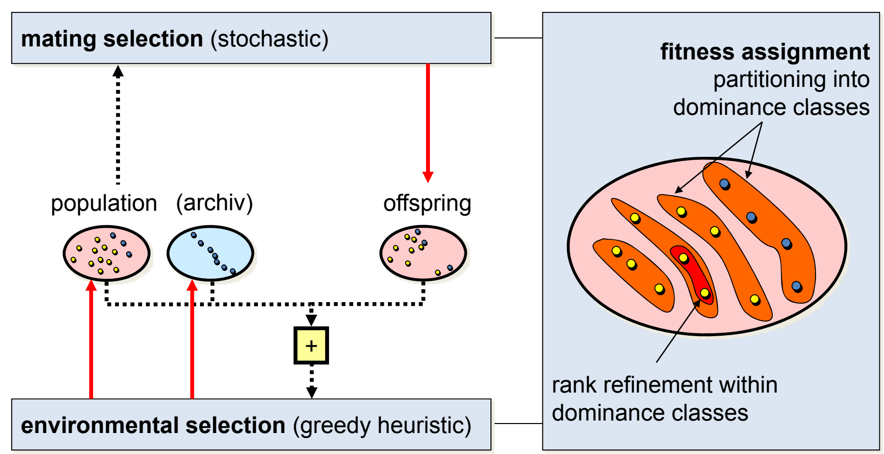
Aggregation-Based: Multistart Constraint Method

Underlying concept:

- Convert all objectives except of one into constraints
- Adaptively vary constraints



General Scheme of Dominance-Based EMO



Note: good in terms of set quality = good in terms of search?

Ranking of the Population Using Dominance

... goes back to a proposal by David Goldberg in 1989.
... is based on pairwise comparisons of the individuals only.

- **dominance rank:** by how many individuals is an individual dominated?
  MOGA, NPGA
- **dominance count:** how many individuals does an individual dominate?
  SPEA, SPEA2
- **dominance depth:** at which front is an individual located?
  NSGA, NSGA-II

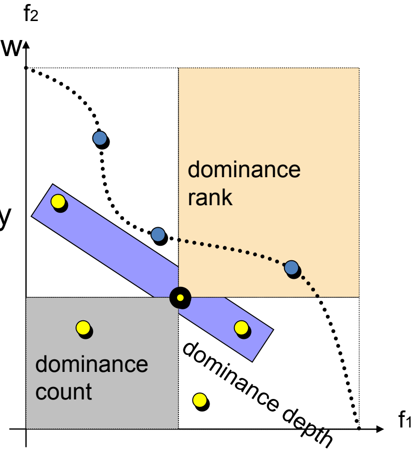


Illustration of Dominance-based Partitioning

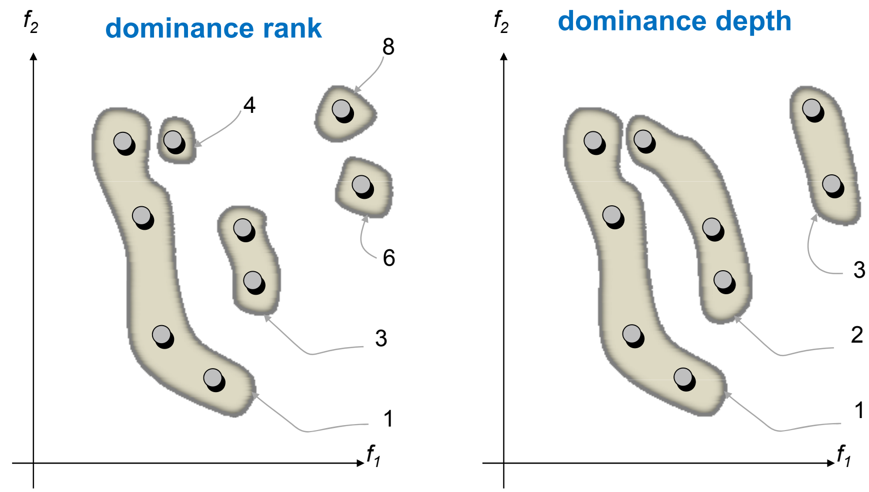


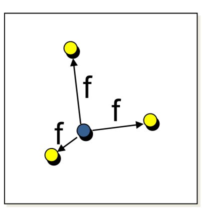
Refinement of Dominance Rankings

Goal: rank incomparable solutions within a dominance class

❶ Density information (good for search, but usually no refinements)

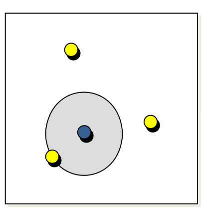
Kernel method

density = function of the distances



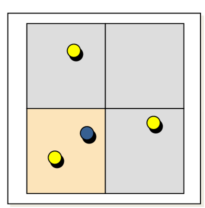
k-th nearest neighbor

density = function of distance to k-th neighbor



Histogram method

density = number of elements within box

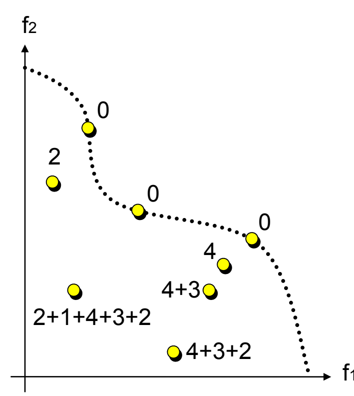


❷ Quality indicator (good for set quality): soon...

Example: SPEA2 Dominance Ranking

Basic idea: the less dominated, the fitter...

Principle: first assign each solution a weight (strength), then add up weights of dominating solutions



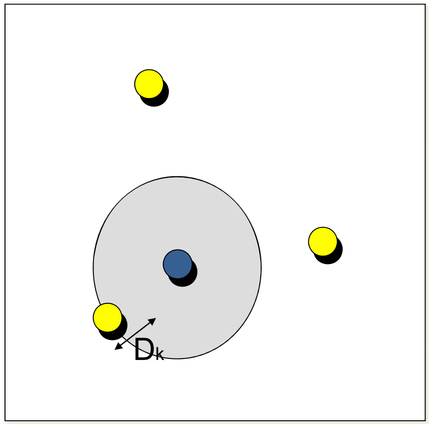
- S (strength) = #dominated solutions
- R (raw fitness) = $\sum$ strengths of dominators

Example: SPEA2 Diversity Preservation

Density Estimation

k-th nearest neighbor method:

- Fitness = R + 1 / (2 + D_k), where 1 / (2 + D_k) < 1
- D_k = distance to the k-th nearest individual
- Usually used: k = 2



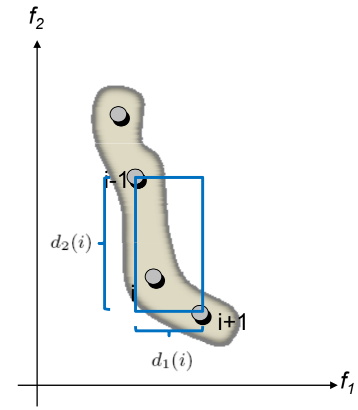
Example: NSGA-II Diversity Preservation

Density Estimation

crowding distance:

- sort solutions wrt. each objective
- crowding distance to neighbors:

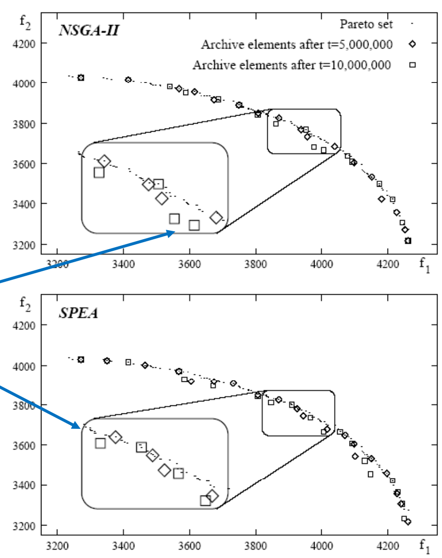
$$d(i) = \sum_{\text{obj. } m} |f_m(i-1) - f_m(i+1)|$$



SPEA2 and NSGA-II: Cycles in Optimization

Selection in SPEA2 and NSGA-II can result in *deteriorative* cycles

non-dominated solutions already found can be lost



1126

Hypervolume-Based Selection

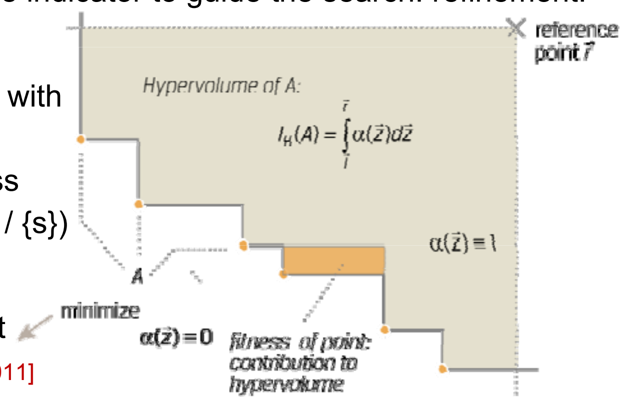
Latest Approach (SMS-EMOA, MO-CMA-ES, HypE, …)

use hypervolume indicator to guide the search: refinement!

Main idea

Delete solutions with the smallest hypervolume loss $d(s) = I_H(P) - I_H(P / \{s\})$ iteratively

But: can also result in cycles [Judt et al. 2011]



Moreover: HypE [Bader and Zitzler 2011]

- Sampling
- Contribution if more than 1 solution deleted

Variation in EMO

- At first sight not different from single-objective optimization
- Most algorithm design effort on selection until now
- But: convergence to a set ≠ convergence to a point

Open Question:

- how to achieve fast convergence to a set?

Related work:

- multiobjective CMA-ES [Igel et al. 2007] [Voß et al. 2010]
- set-based variation [Bader et al. 2009]
- set-based fitness landscapes [Verel et al. 2011]

Overview

The Big Picture

Basic Principles of Multiobjective Optimization

- algorithm design principles and concepts
- performance assessment

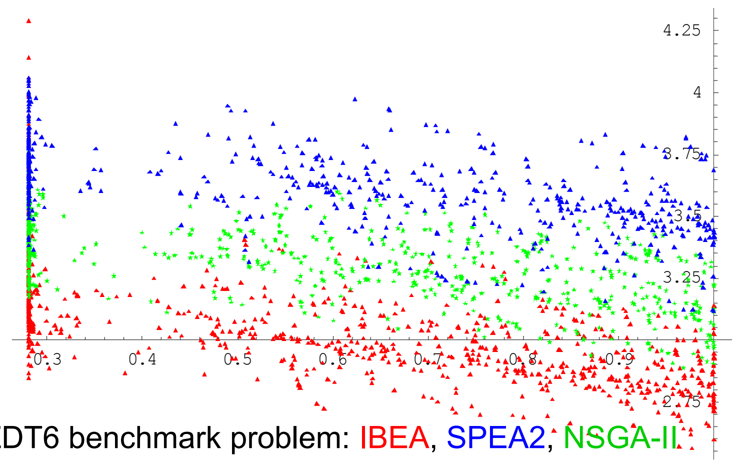
Selected Advanced Concepts

- indicator-based EMO
- preference articulation

A Few Examples From Practice

Once Upon a Time...

... multiobjective EAs were mainly compared visually:



ZDT6 benchmark problem: IBEA, SPEA2, NSGA-II

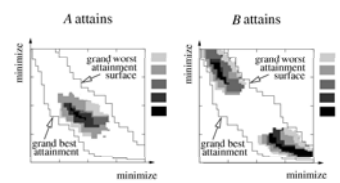
Two Approaches for Empirical Studies

Attainment function approach:

- Applies statistical tests directly to the samples of approximation sets
- Gives detailed information about how and where performance differences occur

Quality indicator approach:

- First, reduces each approximation set to a single value of quality
- Applies statistical tests to the samples of quality values

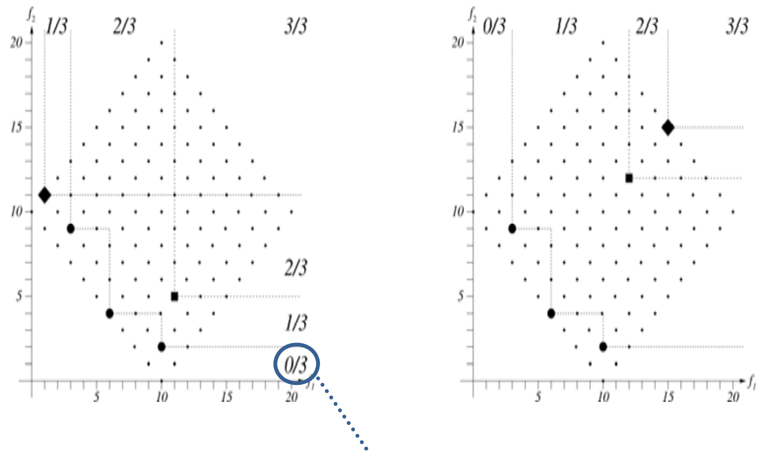


Indicator	A	B
Hypervolume indicator	6.3431	7.1924
ϵ-indicator	1.2090	0.12722
R_2 indicator	0.2434	0.1643
R_3 indicator	0.6454	0.3475

see e.g. [Zitzler et al. 2003]

Empirical Attainment Functions

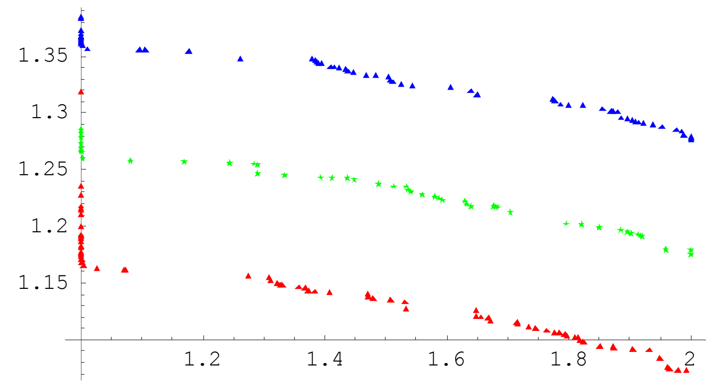
three runs of two multiobjective optimizers



frequency of attaining regions

Attainment Plots

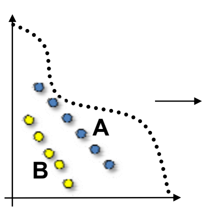
50% attainment surface for IBEA, SPEA2, NSGA2 (ZDT6)



latest implementation online at
http://eden.dei.uc.pt/~cmfonsec/software.html
see [Fonseca et al. 2011]

Quality Indicator Approach

Goal: compare two Pareto set approximations A and B



→

	A	B
hypervolume	*432.34*	*420.13*
distance	*0.3308*	*0.4532*
diversity	*0.3637*	*0.3463*
spread	*0.3622*	*0.3601*
cardinality	*6*	*5*

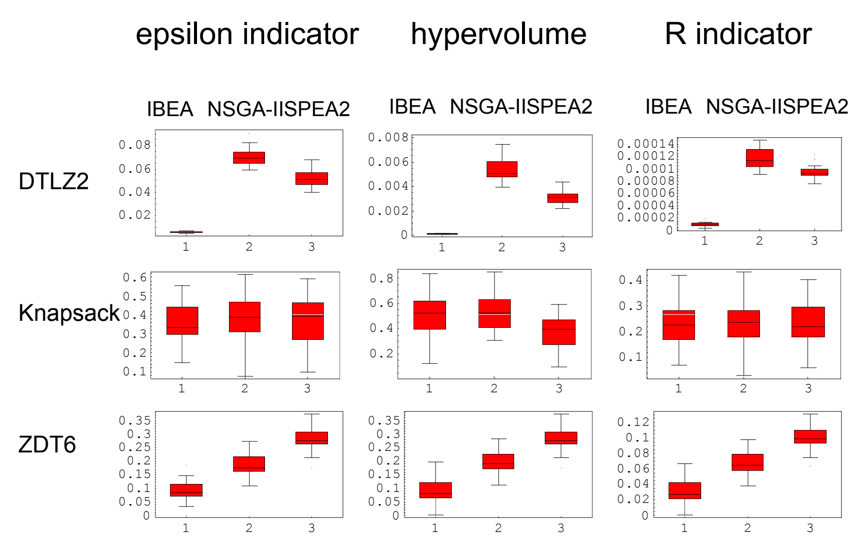
→ "**A** better"

Comparison method C = quality measure(s) + Boolean function

A, B —quality measure→ $\mathbb{R}^n$ —Boolean function→ statement

reduction **interpretation**

Example: Box Plots



Statistical Assessment (Kruskal Test)

ZDT6
Epsilon

is better than →	IBEA	NSGA2	SPEA2
IBEA		~0 ☺	~0 ☺
NSGA2	1		~0 ☺
SPEA2	1	1	

Overall p-value = 6.22079e-17.
Null hypothesis rejected (alpha 0.05)

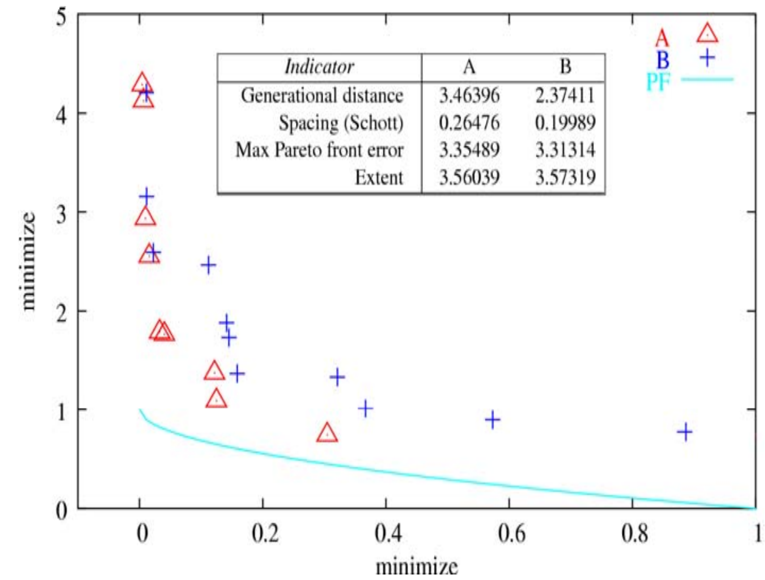
DTLZ2
R

is better than →	IBEA	NSGA2	SPEA2
IBEA		~0 ☺	~0 ☺
NSGA2	1		1
SPEA2	1	~0 ☺	

Overall p-value = 7.86834e-17.
Null hypothesis rejected (alpha 0.05)

Knapsack/Hypervolume: H0 = No significance of any differences

Problems With Non-Compliant Indicators



Indicator	A	B
Generational distance	3.46396	2.37411
Spacing (Schott)	0.26476	0.19989
Max Pareto front error	3.35489	3.31314
Extent	3.56039	3.57319

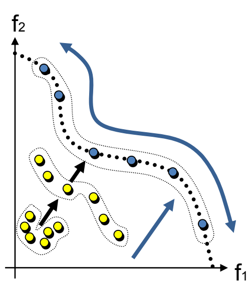
What Are Good Set Quality Measures?

There are **three aspects** [Zitzler et al. 2000]

Comparing different optimization techniques experimentally always involves the notion of performance. In the case of multiobjective optimization, the definition of quality is substantially more complex than for single-objective optimization problems, because the optimization goal itself consists of multiple objectives:

- The distance of the resulting nondominated set to the Pareto-optimal front should be minimized.
- A good (in most cases uniform) distribution of the solutions found is desirable. The assessment of this criterion might be based on a certain distance metric.
- The extent of the obtained nondominated front should be maximized, i.e., for each objective, a wide range of values should be covered by the nondominated solutions.

In the literature, some attempts can be found to formalize the above definition (or parts



Wrong! [Zitzler et al. 2003]

An infinite number of unary set measures is needed to detect in general whether A is better than B

1129

Set Quality Indicators

Open Questions:

- how to design a good benchmark suite?
- are there other unary indicators that are (weak) refinements?
- how to achieve good indicator values?

Overview

Basic Principles of Multiobjective Optimization

- algorithm design principles and concepts
- performance assessment

Selected Advanced Concepts

- indicator-based EMO
- preference articulation

A Few Examples From Practice

Indicator-Based EMO: Optimization Goal

When the goal is to maximize a unary indicator…

- we have a single-objective set problem to solve
- but what is the optimum?
- important: population size μ plays a role!

Multiobjective Problem → Indicator → Single-objective Problem

Optimal μ-Distribution:

A set of μ solutions that maximizes a certain unary indicator I among all sets of μ solutions is called optimal μ-distribution for I. [Auger et al. 2009a]

Optimal μ-Distributions for the Hypervolume

Hypervolume indicator refines dominance relation

$\Longrightarrow$ most results on optimal μ-distributions for hypervolume

Optimal μ-Distributions (example results)

[Auger et al. 2009a]:

- contain equally spaced points iff front is linear
- density of points $\propto \sqrt{-f'(x)}$ with f' the slope of the front

[Friedrich et al. 2011]:

optimal μ-distributions for the hypervolume correspond to ε-approximations of the front

OPT	$1+\frac{\log(\min\{A/a, B/b\})}{n}$
HYP	$1+\frac{\sqrt{A/a}+\sqrt{B/b}}{n-4}$
logHYP	$1+\frac{\sqrt{\log(A/a)\,\log(B/b)}}{n-2}$

Selected Advanced Concepts

- indicator-based EMO
- preference articulation

A Few Examples From Practice

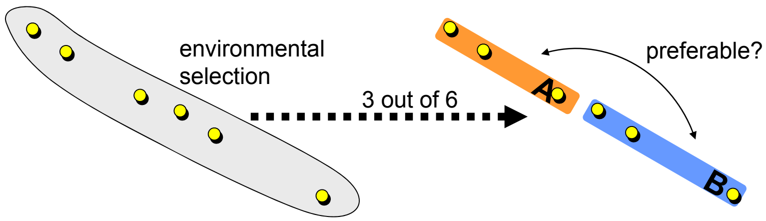
Articulating User Preferences During Search

What we thought: EMO is preference-less

[Zitzler 1999]

> given by the DM.
>
> **Search before decision making:** Optimization is performed without any preference information given. The result of the search process is a set of (ideally Pareto-optimal) candidate solutions from which the final choice is made by the DM.
>
> **Decision making during search:** The DM can articulate preferences during

What we learnt: EMO just uses weaker preference information

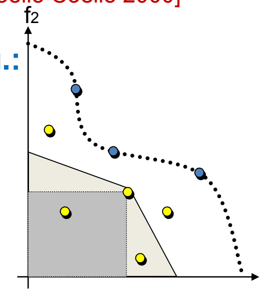


Incorporation of Preferences During Search

Nevertheless...

- the more (known) preferences incorporated the better
- in particular if search space is too large

[Branke 2008], [Rachmawati and Srinivasan 2006], [Coello Coello 2000]



❶ **Refine/modify dominance relation, e.g.:**

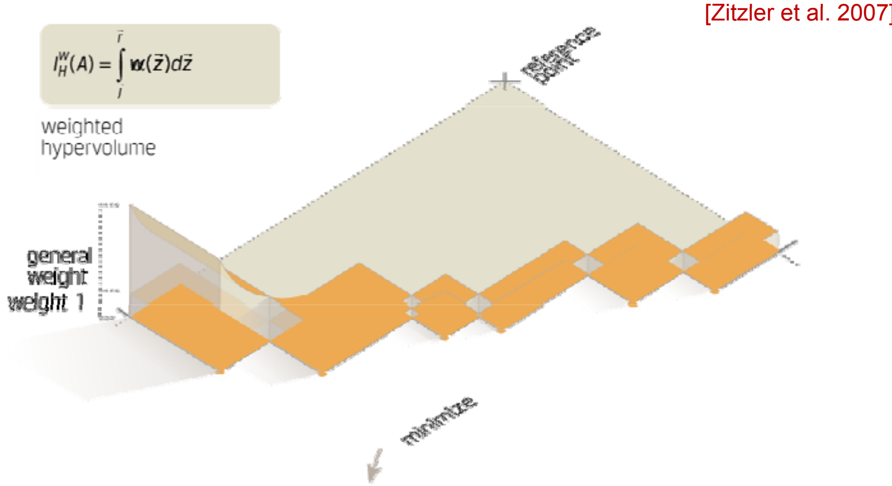
- using goals, priorities, constraints [Fonseca and Fleming 1998a,b]
- using different types of cones [Branke and Deb 2004]

❷ **Use quality indicators, e.g.:**

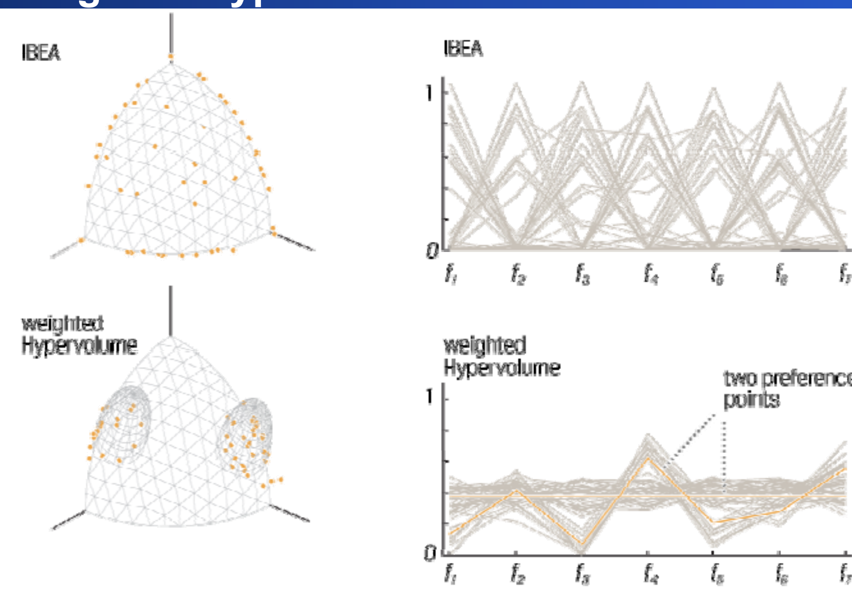
- based on reference points and directions [Deb and Sundar 2006, Deb and Kumar 2007]
- based on binary quality indicators [Zitzler and Künzli 2004]
- based on the hypervolume indicator (now) [Zitzler et al. 2007]

Example: Weighted Hypervolume Indicator

[Zitzler et al. 2007]



Weighted Hypervolume in Practice



[Auger et al. 2009b]

Instructor Biography

Dimo Brockhoff

System Modeling and Optimization Team (sysmo)
Laboratoire d'Informatique (LIX)
École Polytechnique
91128 Palaiseau Cedex
France

After obtaining his diploma in computer science (Dipl. Inform.) from University of Dortmund, Germany in 2005, Dimo received his PhD (Dr. sc. ETH) from ETH Zurich, Switzerland in 2009. Between June 2009 and November 2010 he was a postdoctoral researcher at INRIA Saclay Ile-de-France in Orsay, France. Since November 2010 he has been a postdoctoral researcher at LIX, Ecole Polytechnique within the CNRS-Microsoft chair "Optimization for Sustainable Development (OSD)" in Palaiseau, France. His research interests are focused on evolutionary multiobjective optimization (EMO), in particular on many-objective optimization and theoretical aspects of indicator-based search.
