Mode-dependent Lyapunov function
Discrete-time systems

A B S T R A C T

The paper deals with the stability properties of linear discrete-time switched systems with polytopic sets of modes. The most classical way of studying the uniform asymptotic stability of such a system is to check for the existence of a quadratic Lyapunov function. It is known from the literature that letting the Lyapunov function depend on the time-varying switching parameter improves the chance that a quadratic Lyapunov function exists. Our objective is to compare different notions of quadratic stability. The contribution of this paper is twofold. In the first part we consider switching systems satisfying a certain non-degeneracy assumption and we prove that, for such systems, no gain in the stability analysis is obtained if we allow the Lyapunov function to depend explicitly also on time. In the second part we consider the case where the non-degeneracy assumption is violated. We prove that in this case allowing the Lyapunov function to depend on time is less conservative. We also show that new LMI conditions can be used in order to characterize the existence of a time-dependent quadratic Lyapunov function. Moreover in the paper we discuss the case where the variation of the switching parameter is bounded by a prescribed constant between two subsequent times.

1. Introduction

This paper is devoted to linear discrete-time systems

\[ x(k + 1) = A_\xi(x(k)), \quad (1) \]

where \( \xi(k) \in \Xi \subset \mathbb{R}^d \) and \( x(k) \in \mathbb{R}^d \) for every \( k \in \mathbb{N} \). We will refer to \( k \mapsto \xi(k) \) as to a switching function (\( \xi(k) \) being the switching parameter). We denote by \( \mathcal{A}_\Xi \) the set of admissible modes, i.e.,

\[ \mathcal{A}_\Xi = \{ A_\xi | \xi \in \Xi \}. \]

Most of the paper will deal either with the case where \( \mathcal{A}_\Xi \) is finite or with the case where \( \mathcal{A}_\Xi \) is a convex polytope, i.e., the convex hull of finitely many matrices. Dynamical systems described by (1) with \( \mathcal{A}_\Xi \) a convex polytope are also called polytopic discrete-time systems in the literature [1,2].

Historically, the stability of this class of dynamical systems has been analyzed using the concept of quadratic stability, which we shall call static quadratic stability to avoid confusion with what follows. This notion was inspired by Barmish [3] where Lyapunov functions quadratic in the state and independent of the switching parameter were used for the first time. The main advantage in using such particular Lyapunov functions is the fact that necessary and sufficient conditions for quadratic stability can be formulated in terms of algebraic Riccati equations or linear matrix inequalities (LMIs) [4]. The available solvers make the solutions proposed in this context numerically tractable. Looking for more general Lyapunov functions has received special attention during the last decades in order to derive checkable stability conditions that are more general than those based on static quadratic stability. LMI stability conditions using Lyapunov functions quadratic in the state but with a linear dependence with respect to the switching parameter have been developed in [5]. These conditions are proved to be necessary and sufficient for the existence of this kind of Lyapunov functions and can also be used for design problems (control, state reconstruction, etc.). At the expense of more computational effort, less conservative conditions have been proposed in [6] using quadratic Lyapunov functions depending on several past values of the switching parameters. Advances in the classification of sufficient LMI conditions for stability have been proposed in [7]. In recent years, stability analysis has also been carried out in the framework of the so-called joint spectral radius, a measure of the maximal asymptotic growth rate [8,9]. Despite its natural interpretation and the fact that it leads to a necessary and sufficient stability condition, the joint spectral radius is difficult to...
compute. A procedure for approximating the joint spectral radius with arbitrary high accuracy is provided for the case of finite sets of matrices; however, of course, higher accuracy comes at larger computational cost.

A question of interest is the following: can one expect an improvement of the results in [5] by considering other quadratic Lyapunov functions (not necessarily linear with respect to the switching parameter and not necessarily time-independent)? In the case of linear time-varying (LTV) systems \( k \mapsto \xi(k) \) fixed it is known that stability is equivalent to the existence of a time-varying quadratic Lyapunov function (see [10]). For LTV’s, therefore, time-varying quadratic Lyapunov functions are not equivalent to time-invariant ones as a tool to check stability. Answering whether this is still the case for switched linear discrete-time systems does not seem to be immediate. To this end, we focus in this paper on three criteria of stability. The first one is called Parameter Dependent quadratic stability (PD-quadratic stability). It refers to checking stability by mean of Lyapunov function quadratic in the state and dependent on the switching parameter but without any specified structure. The second one is called Parameter and Time Dependent quadratic stability (PTD-quadratic stability). It refers to Lyapunov functions that are quadratic in the state and depend explicitly on both the time and the parameters. The last one, and a priori the less costlier to check, is the so-called poly-quadratic stability introduced in [5] and which refers to Lyapunov functions quadratic in the state and linear in the switching parameter.

The contribution of this paper is twofold. First, we prove that all these criteria are equivalent in the non-degenerate case, namely when there exists \( \xi \in \mathcal{S} \) such that \( A_1 \) is invertible (see Proposition 4 and Theorem 6). Such an assumption is not restrictive when (1) is obtained by discretization of a continuous-time system. Second, in the degenerate case, we introduce the notion of eventual accessible sets and we show that it leads to a relaxation of the LMI conditions to check stability of switched linear systems that are not PD-quadratically stable (see Theorem 14). We also discuss the case where parameter variation is bounded.

It is known that available necessary and sufficient stability conditions for switched systems (such as the joint spectral radius [9] or those based on Lyapunov functions for difference inclusions [11,12]) are difficult to check numerically. A popular approach has been to try to approximate these conditions by a class of conditions that we can efficiently solve using convex optimization and in particular semidefinite programming. Semidefinite programs (SDPs) can be solved with arbitrary accuracy in polynomial time and lead to efficient computational methods. Our above-mentioned contributions imply the following: (i) in the non-degenerate case it is redundant (and numerically costlier) to consider time-dependent Lyapunov functions or Lyapunov functions which depend nonlinearly on the switching parameter; (ii) in the degenerate case time-dependent quadratic Lyapunov functions give a less conservative test for stability (see Example 17), which can still be formulated in terms of LMIs.

The paper is organized as follows. In Section 2 we introduce the main definitions and we discuss the equivalence of asymptotic stability under convexification of the set of state-space matrices. In Section 3.1, we prove the equivalence between the stability criteria introduced above and we discuss the case where parameter variation is bounded. We also illustrate in the discrete time setting the well-known fact that uniformly asymptotically stable switched systems which do not admit quadratic Lyapunov functions exist showing that a system can be uniformly asymptotically stable without being poly-quadratically stable (or PTD-quadratically stable). The notion of eventual accessibility and the relaxed LMIs conditions are introduced in Section 4. This allows to compare the previous notions of quadratic stability in the general case. We end the paper by a conclusion.

2. Preliminaries

Fix \( d \in \mathbb{N} \). Let \( \{e_1, \ldots, e_d\} \) be the canonical basis of \( \mathbb{R}^d \) and denote by \( M_d(\mathbb{R}) \) the set of all real \( d \times d \) matrices. Recall that a partial order on \( M_d(\mathbb{R}) \) is defined as follows: Given \( A, B \in M_d(\mathbb{R}) \), we write \( A \preceq B \) if \( A - B \) is negative semidefinite. A function with values in \( M_d(\mathbb{R}) \) is said to be convex if it is so with respect to such order. We say that \( A > 0 \) on a subset \( \Sigma \subset \mathbb{R}^d \) if \( \forall x \in \Sigma \) \( x^T A x > 0 \). The Euclidean norm in \( \mathbb{R}^d \) and that induced in \( M_d(\mathbb{R}) \) are both denoted by \( \| \cdot \| \). A function \( w : \mathbb{R} \to M_d(\mathbb{R}) \) defined for all \( x > 0 \) is said to be of order \( k (k \in \mathbb{N}) \) if \( \lim_{t \to \infty} \| w(t) \| = 0 \). In this case we write \( w(t) = \mathcal{O}(e^{-k}) \).

Let \( \mathcal{A} = \{ A_1, \ldots, A_M \} \) be a map from \( \mathcal{S} \) to \( M_d(\mathbb{R}) \). As stated in the introduction, we consider the dynamical system (1) with \( A_\Sigma \) the set of admissible modes, i.e., \( A_\Sigma = \{ A_1 \in \mathcal{A} \mid \xi \in \mathcal{S} \} \). Without loss of generality, in the case where \( A_\Sigma \) is finite, we assume that \( m = 1 \) and \( \mathcal{S} = \{ 1, \ldots, M \} \) for some \( M \in \mathbb{N} \) so that \( A_\Sigma = \{ A_1, \ldots, A_M \} \). We also define \( \bar{A}_\Sigma = \{ A_1, \ldots, A_M \} \) where \( \bar{A}_\Sigma \) is a convex map, we denote by \( \{ A_1, \ldots, A_M \} \) the set of its vertices and we assume that \( m = M \), \( \mathcal{S} = \text{conv}\{e_1, \ldots, e_M\} \), and that \( A \) is the linear map satisfying \( A_i = A_{i\Sigma} \). In this case we say that system (1) is polytopic.

The notion of uniform asymptotic stability of a discrete-time switched system is recalled in the following definition.

Definition 1. We say that (1) is uniformly asymptotically stable (UAS) if for every \( \forall x(0) \in \mathbb{R}^d \) the solution to (1) converges to zero uniformly with respect to \( \{ \xi(k) \}_{k \in \mathbb{N}} \subset \mathcal{S} \), i.e., for every \( \varepsilon > 0 \) there exists \( K \in \mathbb{N} \) such that for every \( \{ \xi(k) \}_{k \in \mathbb{N}} \subset \mathcal{S} \) we have \( \| x(k) \| < \varepsilon \) for \( k > K \) and if, moreover, for every \( R > 0 \) there exists \( r > 0 \) such that \( \| x(k) \| < R \) for every \( \{ \xi(k) \}_{k \in \mathbb{N}} \subset \mathcal{S} \) and every \( k \in \mathbb{N} \) provided that \( \| x(0) \| < r \).

Because of the linear nature of the dynamics of (1), it is well known that (1) is uniformly exponentially stable if and only if it is UAS (indeed, if \( ad \) only if the origin is attractive, see for instance [13, Section 5.2]).

2.1. Lyapunov functions

A classical sufficient condition for the UAS of (1) is the existence of a (parameter–dependent) quadratic Lyapunov function.

Definition 2. We say that (1) is parameter–dependent quadratically stable (PD-quadratically stable) if there exist three positive constants \( \alpha_0, \alpha_1, \alpha_2 \) and a Lyapunov function

\[
V(x, \xi) = x^T P_1 x
\]

with \( \mathcal{S} \ni \xi \mapsto P_1 \in M^{d \times d} \) such that

\[
\alpha_1 \| x \|^2 \leq V(x, \xi) \leq \alpha_2 \| x \|^2, \quad x \in \mathbb{R}^d, \; \xi \in \mathcal{S},
\]

and

\[
V(A_1 x, \eta) - V(x, \xi) \leq -\alpha_0 \| x \|^2, \quad x \in \mathbb{R}^d, \; \xi, \eta \in \mathcal{S}.
\]

We recall below the notion of poly-quadratic stability, introduced in [5], which corresponds to the special case where, in the definition above, system (1) is polytopic and V is linear with respect to \( \xi \).

Definition 3. Let (1) be polytopic. We say that (1) is poly-quadratically stable if there exists a function \( V \) satisfying (2)–(4) that is linear with respect to \( \xi \), i.e., \( P_1 = \sum_{i=1}^M \xi_i P_i \).

For polytopic systems it turns out that, on the one hand, UAS is equivalent to the same property for the system having as modes the vertices of \( A_\Sigma \) and, on the other hand, PD-quadratic stability and poly-quadratic stability are equivalent. These facts
are detailed in the following proposition, which is essentially a collection of known results.

**Proposition 4.** Let \((1)\) be polytopic. Then \((1)\) is UAS if and only if the finite system with modes \(\{A_1, \ldots, A_m\}\) is UAS. Moreover, \((1)\) is polyquadratically stable if and only if there exist a scalar \(\alpha_0 > 0\) and \(M\) symmetric matrices \(P_1, \ldots, P_M\) such that

\[
P_i > 0 \quad \forall i \in \{1, \ldots, M\} \tag{5}
\]

\[
P_i^T A_i - P_i \preceq -\alpha_0 I, \quad \forall i, j \in \{1, \ldots, M\}. \tag{6}
\]

In particular, \((1)\) is polyquadratically stable if and only if it is PD-quadratically stable.

**Proof.** The first part of the statement follows from classical results characterizing stability of discrete-time switched systems in terms of the joint spectral radius. It is well known that for a bounded set of matrices \(A_2\), the uniform asymptotic stability of \((1)\) is equivalent to the property that the joint spectral radius

\[
\rho(A_2) = \limsup_{k \to \infty} \max_{\xi \in \mathbb{E}} \|A_{k+1} \cdots A_{kM}\|^k
\]

is strictly smaller than one. The claimed equivalence then follows from the equality

\[
\rho(\text{conv}(A_1, \ldots, A_M)) = \rho((A_1 \cdots A_M)),
\]

which has been observed in [14] (see also [9,15] and, for related discussions [16,17]).

The second part of the statement, which expresses polyquadratic stability in terms of finitely many LMIs, trivially follows from [5]. (See also [18, Theorem 2].)

Finally, concerning the last part of the statement, PD-quadratic stability implies by definition conditions (5)–(6) and therefore polyquadratic stability. □

Motivated by the characterization of asymptotic stability of LTVs in terms of existence of time-varying quadratic Lyapunov functions (see [10]), we introduce the following \((a \text{ priori})\) weaker notion.

**Definition 5.** We say that \((1)\) is parameter- and time-dependent quadratically stable (PTD-quadratically stable) if there exist three positive constants \(\alpha_0, \alpha_1, \alpha_2\) and a Lyapunov function

\[
V(k, x, \xi) = x^T P_{k,\xi} x \tag{7}
\]

such that

\[
\alpha_1 \|x\|^2 \leq V(k, x, \xi) \leq \alpha_2 \|x\|^2, \quad x \in \mathbb{R}^d, \quad \xi \in \mathbb{E}, \tag{8}
\]

and for every \(x(0) \in \mathbb{R}^d\), every \(\{\xi(k)\}_{k \in \mathbb{N}} \subset \mathbb{E}\), and every \(k \in \mathbb{N}\), we have

\[
V(k + 1, x(k + 1), \xi(k + 1)) - V(k, x(k), \xi(k)) \leq -\alpha_0 \|x(k)\|^2. \tag{9}
\]

3. The nondegenerate case

In this section we investigate quadratic stability under the hypothesis that a mode of system \((1)\) is nondegenerate. Notice that such hypothesis is very natural since it is always satisfied when \((1)\) is obtained by discretization of a continuous-time system. We first compare the notions introduced in the previous section and we then adapt the result to systems satisfying particular constraints on the switching laws.

3.1. Equivalence between different notions of quadratic stability

The following theorem states the equivalence between the three notions of quadratic stability introduced in the previous section, under the hypothesis that a mode of system \((1)\) is nondegenerate. The case where the hypothesis does not necessarily hold is considered in Section 4. Motivated by the first part of Proposition 4, we state the result only for finite systems. A straightforward adaptation to the polytopic case is given in Remark 7.

**Theorem 6.** Let \((1)\) be finite. Assume that there exists \(\tilde{\xi} \in \mathbb{E}\) such that \(A_2\) is invertible. Then \((1)\) is PTD-quadratically stable if and only if it is PD-quadratically stable.

**Proof.** It is clear by the definitions given in Section 2 that if \((1)\) is PD-quadratically stable then it is PTD-quadratically stable. (Notice that we do not need, for this part of the argument, to assume the existence of \(\tilde{\xi} \in \mathbb{E}\) such that \(\det(A_2) \neq 0\).)

Assume then that \((1)\) is PTD-quadratically stable and fix \((k, \xi, x) \mapsto V(k, \xi, x)\) and \((k, \xi) \mapsto P_{k,\xi}\) as in Definition 5. We are left to prove that \((1)\) is PD-quadratically stable.

Given \(k \in \mathbb{N}\), take \(\tilde{\xi}(j) = \tilde{\xi}\) for \(j < k\) so that for every \(\tilde{k} \in \mathbb{R}^d\) we can choose \(x(0)\) in such a way that the solution of \((1)\) satisfies \(x(k) = \tilde{x}\). Considering any choice of \(\tilde{x}\) and \(\tilde{\xi}(j)\) in \(1, \ldots, M\), we deduce from (9) and the arbitrariness of \(\tilde{x}\) that

\[
A_1^j P_{k+1, j} A_i - P_{k,i} \leq -\alpha_0 I, \quad i, j \in \{1, \ldots, M\}. \tag{10}
\]

Define \(\Omega(k) = (P_{k,1}, \ldots, P_{k,M})\) for every \(k \in \mathbb{N}\). Notice that \(\{\Omega(k)\}_{k \in \mathbb{N}}\) is a bounded sequence in \((M(d)^d)^N\), due to [8]. We can thus extract a converging subsequence \(\{\Omega(k_i)\}_{i \in \mathbb{N}}\).

For every \(l \in \mathbb{N}\), let us consider a time-independent \(M\)-tuple of symmetric positive definite matrices of the form

\[
P_{l,\Omega_i} = \sum_{k=k_i}^{k_{i+1}-1} P_{k,j}, \quad j \in \{1, \ldots, M\}.
\]

Taking \(l\) large enough, we can assume

\[
\frac{-\alpha_0}{2} I \leq A_1^j (P_{k_{i+1}-1,j} - P_{k_{i},j})A_i \leq \frac{-\alpha_0}{2} I, \quad i, j \in \{1, \ldots, M\}.
\]

Then, for every \(i, j \in \{1, \ldots, M\}\) and every \(l\) large enough,

\[
A_1^j P_{l,\Omega_i} A_i - P_{l,i} = A_1^j P_{k,j} A_i - P_{k,i} + \sum_{k=k_i}^{k_{i+1}-1} A_1^j P_{k+1, j} A_i - P_{k,i}
\]

\[
\leq A_1^j (P_{k+1,j} - P_{k,j})A_i + \sum_{k=k_i}^{k_{i+1}-1} A_1^j P_{k+1, j} A_i - P_{k,i}
\]

\[
\leq - \left( k_{i+1} - k_i - \frac{1}{2} \right) \alpha_0 I \leq -\frac{-\alpha_0}{2} I \text{ Id}.
\]

Setting \(\hat{\alpha} = \frac{-\alpha_0}{2}\) and \(P_{l,\Omega_i}^+ = P_{l,\Omega_i}^+\) for \(i = 1, \ldots, M\) and \(l\) large (independent of \(i\) and \(j\)), we have

\[
A_1^j P_{l,\Omega_i}^+ A_i - P_{l,i}^+ \leq -\hat{\alpha} I, \quad i, j \in \{1, \ldots, M\}, \tag{11}
\]

which concludes the proof of Theorem 6. □

**Remark 7.** Theorem 6 can be extended to the case where \((1)\) is polytopic. Indeed, assume that there exists \(\tilde{\xi} \in \mathbb{E} = \text{conv}(\xi_1, \ldots, \xi_m)\) such that \(\det(A_2) \neq 0\) and that \((1)\) is PTD-quadratically stable. Then the finite system having \(A_1, \ldots, A_m, A_2\) as modes is PTD-quadratically stable and, by Theorem 6, PD-quadratically stable. It follows by Proposition 4 that \((1)\) is PD-quadratically stable.

3.2. \(\delta\)-stability

We consider in this section the problem of detecting through quadratic Lyapunov functions the stability of polytopic systems whose switching functions have some common bound on the
speed of variation. More precisely, given \( \delta > 0 \), we say that \( \xi : \mathbb{N} \to \mathcal{S} \) is a \( \delta \)-switching function if \( \| \xi(k + 1) - \xi(k) \| < \delta \) for every \( k \in \mathbb{N} \). This constraint has a practical justification. Indeed, the class of dynamical systems we consider here is also studied in the context of the so-called linear parameter varying (LPV) systems where a scheduling parameter is assumed to vary arbitrarily within a polytopic set. In practice, however, there are often limitations on the rate of parameter variation. Two of many examples for limited-variation parameters in LPV systems are the amount of fuel in an airplane for flight control systems or the engine speed in engine control systems. Taking these limitations into account leads to less conservative results. This fact has been recognized in the literature and is incorporated in other control methods for LPV systems (see [19–21] and references therein).

We say that (1) is \( \delta \)-UAS if it is uniformly asyptotically stable with respect to the class of \( \delta \)-switching functions. Analogously, the notion of \( \delta \)-PTD-quadra
tically stable admits a straightforward counterpart for \( \delta \)-switching functions: we speak of \( \delta \)-PTD-quadra
tically stability. As for PD-quadra
tically stability, we can define the corresponding notion of \( \delta \)-PD-quadra
tically stability by replacing (4) by

\[
V(A_\xi x, \eta) - V(x, \xi) \leq -\alpha_0 \| x \|^2, \quad x \in \mathbb{R}^d, \; \xi, \eta \in \mathcal{S},
\]

Finally, in order to extend the notion of poly-quadratic stability to the case of a polytopic system (1), we replace the assumption that the Lyapunov function is linear on \( \mathcal{S} \) by the requirement that it is just piecewise affine, in the following sense. We say that (1) is \( (\delta, \rho) \)-poly-quadratic stable if it is \( \delta \)-PD-quadra
tically stable with a Lyapunov function which is continuous on \( \mathcal{S} \) and affine on every simplex of a tessellation of \( \mathcal{S} \) whose simplices have all di
dameter smaller than \( \rho \). We recall that a simplex of dimension \( n \) is a polytope with \( n + 1 \) vertices \( w_1, \ldots, w_{n+1} \) such that the vectors \( w_1 - w_{n+1}, w_2 - w_{n+1}, \ldots, w_n - w_{n+1} \) are linearly independent, thus a tessellation of \( \mathcal{S} \) is a finite covering of \( \mathcal{S} \) by simplices of dimension \( M - 1 \) (the dimension of \( \mathcal{S} \) whose (rela
tive) interiors are pairwise disjoint. Finally, the diameter of a subset \( S \) of \( \mathbb{R}^d \) is defined as \( \sup_{x,y \in S} \| x - y \| \).

The following holds.

**Theorem 8.** Let (1) be polytopic and assume that there exists \( \bar{\xi} \in \mathcal{S} \) such that \( A_{\bar{\xi}} \) is invertible. If (1) is \( (\delta, \rho) \)-poly-quadratic stable then it is \( \delta \)-PD-quadra
tically stable and \( \delta \)-PTD-quadra
tically stable. Moreover, if (1) is \( \delta \)-PTD-quadra
tically stable then, for every \( \delta' \in (0, \delta) \), there exists \( \rho > 0 \) such that (1) is \( (\delta', \rho) \)-poly-quadratic stable.

**Proof.** The first part of the statement being trivial, assume that (1) is \( \delta \)-PTD-quadra
tically stable and fix \( \alpha_0, \alpha_1, \alpha_2 > 0, (k, \xi) \mapsto P_{k, \xi} \) and \( V(k, x, \xi) = x^T P_{k, \xi} x \) such that \( \alpha_1 \text{Id} \leq P_{k, \xi} \leq \alpha_2 \text{Id} \) for every \( k \in \mathcal{S} \) and

\[
V(k + 1, x(k + 1), \xi(k + 1)) - V(k, x(k), \xi(k)) \\
\leq -\alpha_0 \| x(k) \|^2, \quad k \in \mathbb{N},
\]

for every solution \( x(\cdot) \) of (1) corresponding to a \( \delta \)-switching function \( \xi(\cdot) \).

Fix \( \delta' \) belonging to \( (0, \delta) \). Choose \( \rho > 0 \) such that

\[
\delta' + 2\rho < \delta.
\]

Fix a tessellation of \( \mathcal{S} \) such that the diameter of each of its simplices is smaller than \( \rho \). Denote by \( \mathcal{T} \) the set of simplices of the tessellation and by \( A \) the set of its vertices. Since the function \( \xi \mapsto \det(A_\xi) \) is analytic and, by hypothesis, it does not vanish identically, we deduce that for almost every \( \bar{\xi} \in \mathcal{S} \) the matrix \( A_{\bar{\xi}} \) is invertible. Hence, for every \( \bar{\xi} \in \mathbb{R}^d \), every

\[
\hat{\xi} \in \mathcal{S}
\]

every \( k \in \mathbb{N} \) there exist \( x(0) \) and a \( \delta \)-switching function \( \xi : \mathbb{N} \to \mathcal{S} \) such that the corresponding trajectory \( x(\cdot) \) of (1)

satisfies \( x(k) = \bar{\xi}, \xi(k) = \hat{\xi} \).

Following the same argument as in the proof of Theorem 6 we can show that there exist \( \hat{\alpha} > 0 \) and a family of positive definite matrices \( P_{k, \xi}^* \), \( e \in A \), such that

\[
A_{k, \xi}^* P_{\xi}^* A_{k, \xi} - P_{\xi}^* \leq -\hat{\alpha} \text{Id} \quad \text{on} \; \mathbb{R}^d,
\]

for every \( \xi, \eta \in \mathcal{S} \) such that \( \| \xi - \eta \| < \delta \).

Extend \( P_* \), seen as a matrix-valued function defined on \( A \), to the piecewise affine function \( P_* \) on \( \mathcal{S} \) defined by

\[
\Pi_\xi = \sum_{i=1}^M \lambda_i P_{\xi, i}^* 
\]

where \( e_1, \ldots, e_M \in A \) are the vertices of a simplex in \( A \) and

\[
\sum_{i=1}^M \lambda_i e_i^T = \xi \quad \text{with} \sum_{i=1}^M \lambda_i = 1, \lambda_i \geq 0 \quad \text{for} \; i = 1, \ldots, M.
\]

Consider \( \xi \) and \( \eta \) in \( \mathcal{S} \) such that \( \| \xi - \eta \| < \delta' \). Take \( e_1, \ldots, e_M, e_j \) in \( \mathcal{S} \) as above, with \( \sum_{i=1}^M \lambda_i e_i^T = \xi \) and \( \sum_{i=1}^M \mu_i e_i^T = \eta \). Recall that \( \rho \) has been chosen in such a way that (13) holds true. Hence \( \| e_i^T - e_j^T \| < \delta \) for every \( i, j = 1, \ldots, M \).

Let \( j \) belong to \( \{1, \ldots, M\} \). Notice that the map \( M_d(\mathbb{R}) \ni C \mapsto C^T P_{\xi, j}^* C \) is convex. Hence,

\[
A_{k, \xi}^* \left( \sum_{i=j}^M \mu_i P_{\xi, i}^* \right) A_{k, \xi} - \Pi_\xi = A_{k, \xi}^* \Pi_\xi A_{k, \xi} - \Pi_\xi \leq -\hat{\alpha} \text{Id},
\]

where the last inequality follows from (14). Since the above inequality holds for every \( j \), we conclude that

\[
A_{k, \xi}^* \left( \sum_{i=1}^M \mu_i P_{\xi, i}^* \right) A_{k, \xi} - \Pi_\xi = A_{k, \xi}^* \Pi_\xi A_{k, \xi} - \Pi_\xi \leq -\hat{\alpha} \text{Id},
\]

as required.

**Remark 9.** The proof of the theorem (see, in particular, (13)) shows the following tradeoff in the choice of \( \delta' \) and \( \rho \), for a given \( \delta \)-PTD-quadra
tically stable system: As \( \delta' \) gets close to \( \delta \), \( \rho \) gets small in general; conversely, decreasing \( \delta' \), we can increase \( \rho \), reducing the number of LMI s to be tested.

### 3.3. Asymptotic vs. quadratic stability

We go back here to the general case, without bounds on the speed of variation of the switching parameter \( \xi \). As already mentioned, the equivalent conditions appearing in the statement of Theorem 6 are sufficient for the uniform asymptotic stability of (1). However, they are not necessary. A numerical evidence for this fact was already given in [6], where the authors generalize the notion of PD-quadra
tically stable by considering quadratic Lyapunov functions depending on several past values of the switching parameters, that is,

\[
V(x(0), k, \xi, k(1), \ldots, k(m)) = x(0)^T P_{\xi, k(1)\ldots k(m)} x(0)
\]

It is proved in [6, Theorem 9] that UAS is equivalent to the existence of \( m \in \mathbb{N} \) and \( (\xi_0, \ldots, \xi_m) \mapsto P_{\xi_0\ldots \xi_m} > 0 \) satisfying the LMI s

\[
A_{k, \xi}^* P_{\xi_0\ldots \xi_m} A_{k, \xi} - P_{\xi_0\ldots \xi_m} < 0,
\]

\[
\xi_0, \ldots, \xi_m+1 \in \{1, \ldots, M\}.
\]
Clearly, if there exists a solution of the system of LMIs (16) for some $m \in \mathbb{N}$, then solutions exist for every $m' \geq m$. In [6, Example 29] Lee and Dullerud present a specific 1-parameter family of UAS switched systems and compute numerically the minimal $m$ required to test the stability of the system. The computations show that $m = 0$ is a conservative choice, that is, it does not allow to characterize uniform asymptotic stability. The chosen example “saturates” at $m = 7$, that is, the maximal integer $m$ required to check UAS is 7. It is natural to ask whether examples can be found where the “saturating” $m$ is arbitrarily large (similarly to what happens for the minimal degree of a common polynomial Lyapunov function in the continuous-time case, see [22]). The following proposition gives a positive answer to such question and proposes a construction of UAS systems for which (16) has no solution (for a fixed $m$).

**Proposition 10.** For any fixed integer $m \in \mathbb{N}$ there exists a UAS system of type (1) which does not admit a Lyapunov function of the type (15) satisfying (16).

**Proof.** The proof works by contradiction. The idea is to consider a continuous-time switched system with suitable properties and to time-discretize it. For every time-step the system that is obtained is stable, but the assumption that all such systems satisfy equations of the form (16) leads to a contradiction when the time-step goes to zero (and the discrete systems converge, roughly speaking, to the continuous one).

Take $d = 2$ and $\mathcal{S} = \{1, 2\}$ and assume by contradiction that if (1) is UAS, then there exist positive definite matrices $P_{00}, \ldots, P_{mm}$ for every $(\eta_0, \ldots, \eta_m) \in \{1, 2\}^{m+1}$ such that (16) holds true.

It is well known that there exist uniformly asymptotically stable continuous linear switched systems of the type

$$\dot{x} = u(t)C_1x + (1 - u(t))C_2x, \quad u(t) \in \{0, 1\}, \ x \in \mathbb{R}^2,$$

such that there exist no positive definite matrix $P$ such that $C_i^TP + PC_i \leq 0$ for $i = 1, 2$ (see, e.g., [23]). It is possible, moreover, to assume that $C_1$ and $C_2$ have non-real eigenvalues. (Notice that the exact result appearing in [23] proves the possible nonexistence, for a uniformly asymptotically stable system, of a quadratic Lyapunov function, i.e., of $P > 0$ satisfying $C_i^TP + PC_i < 0$ for $i = 1, 2$. Here we impose a slightly stronger property, since we want to rule out the possibility of a positive definite quadratic function which is non-increasing along trajectories of (17). The result, however, directly follows from the reasoning in [23].)

Let us define, for every $\epsilon > 0$,

$$A_1^\epsilon = e^{\epsilon C_1}, \quad A_2^\epsilon = e^{\epsilon C_2},$$

and consider the corresponding family of discrete systems

$$x(k+1) = A_1^\epsilon(k)x(k), \quad x(k) \in \{1, 2\}.$$  

(18)

Every such system is obviously UAS, because of the uniform asymptotic stability of (17). According to the contradiction hypothesis, let us assume that for every $\epsilon > 0$ there exist $P_{00}^\epsilon, \ldots, P_{mm}^\epsilon > 0$, $(\eta_0, \ldots, \eta_m) \in \{1, 2\}^{m+1}$ such that (16) holds true. Up to a rescaling we can assume $\max_{00 \ldots mm} \|P_{00}^\epsilon, \ldots, P_{mm}^\epsilon\| = 1$ for every $\epsilon > 0$. Thus, by compactness, we can find a suitable sequence $\epsilon_h \rightarrow 0$ such that $P_{00}^\epsilon, \ldots, P_{mm}^\epsilon \rightarrow P_{00}, \ldots, P_{mm}$ for every $(\eta_0, \ldots, \eta_m) \in \{1, 2\}^{m+1}$. Moreover, there exists at least one $(\eta_0, \ldots, \eta_m) \in \{1, 2\}^{m+1}$ such that $P_{00}, \ldots, P_{mm}$ has norm equal to one.

Since, for $\epsilon > 0$ small, we have $A_1^\epsilon = I_d + O(\epsilon)$ for $i = 1, 2$, we deduce that

$$(A_1^\epsilon)^TP_{00}^\epsilon + (P_{00}^\epsilon)^{-1}A_2^\epsilon = P_{00}^{-\epsilon} - P_{mm}^\epsilon + O(\epsilon) < 0$$

for every $(\xi_0, \ldots, \xi_{m+1}) \in \{1, 2\}^{m+2}$, so that, passing to the limit along the sequence $\epsilon_h$, we get

$$P_{00}^{-\epsilon} - P_{mm}^\epsilon \leq 0.$$

Iterating this inequality $m + 1$ times we get

$$P_{00}^{-\epsilon} \leq P_{mm}^\epsilon.$$

Because of the arbitrariness of the $(m + 1)$-tuple $(\xi_0, \ldots, \xi_{m+1})$ in $(1, 2)^{m+2}$, it actually holds

$$(A_1^\epsilon)^TP_{00}^\epsilon + P_{mm}^\epsilon \leq 0$$

for every $(\xi_0, \ldots, \xi_{m+1}) \in \{1, 2\}^{m+2}$ and $\|P\| = 1$.

On the other hand, since, for $\epsilon > 0$ small, we have $A_i^\epsilon = I_d + \epsilon C_i + O(\epsilon^2)$ for $i = 1, 2$, we deduce that

$$(A_i^\epsilon)^TP_{00}^\epsilon + P_{mm}^\epsilon \leq 0$$

for $i = 1, 2$, where $A_i^\epsilon$ is invertible, but also positive definite. Indeed, assume by contradiction that there exists $v \in \mathbb{R}^2 \setminus \{0\}$ such that $v^TPv > 0$. Because of (19), $x^TPx$ could be identically equal to 0 along any trajectory of the switched system starting from $v$. Moreover, since $\|P\| = 1$, any trajectory starting from $v$ should stay in $\mathbb{R}^d$. This would imply that $v$ is an eigenvector of $C_1$ and $C_2$, which is impossible because $C_1$ and $C_2$ have non-real eigenvalues.

Thus $P$ is positive definite and satisfies $C_i^TP + PC_i \leq 0$ for $i = 1, 2$. This contradicts the initial assumption made on $C_1$, $C_2$ and the proposition is proved. \hfill $\square$

4. The degenerate case

We consider here the case in which the non-degeneracy hypothesis appearing in Theorem 6, namely, the existence of $\xi \in \mathcal{S}$ such that $A_i$ is invertible, does not hold. The perfect analogue of Theorem 6 is false in this case, as we will see by a counterexample at the end of this section. Different notions of quadratic stability give rise to non-equivalent tests for asymptotic stability. A special role is played by LMIs which hold on the eventual accessible set, which is introduced in the next section.

4.1. Eventual accessible sets and relaxation of the LMI conditions for stability

Fix $A_1, \ldots, A_m$ in $M_d(\mathbb{R})$. Define $\Sigma_0 = \mathbb{R}^d$ and $\Sigma_k = \cup_{i=1}^M A_i(\Sigma_{k-1}), \ k \in \mathbb{N}$.

Then $\Sigma_k$ is the set of all points of $\mathbb{R}^d$ that can be obtained as evaluation at the time $k$ of a trajectory of the finite system (1).

**Lemma 11.** Fix $A_1, \ldots, A_m$ in $M_d(\mathbb{R})$ and define $\Sigma_k, k \in \mathbb{N}$, as above. Then there exists $k \in \mathbb{N}$ such that $\Sigma_k = \Sigma_k$ for every $k \geq k$.

**Proof.** By construction, each $\Sigma_k$ is the union of finitely many linear subspaces of $\mathbb{R}^d$. We say that a linear subspace $L$ of $\mathbb{R}^d$ is a component of $\Sigma_k$ if every linear subspace containing $L$ and contained in $\Sigma_k$ coincides with $L$.

We associate with each $k \in \mathbb{N}$ and each $\delta \in \{1, \ldots, d\}$, the number $\nu(\delta, k)$ of components of $\Sigma_k$ of dimension $\delta$. For every $k \in \mathbb{N}$, consider the set $D_k = \{\delta \mid \delta \in \{1, \ldots, d\}, \nu(\delta, k) \geq 1\}$, and rewrite its terms in decreasing order $D_k = \{d_1 > d_2 > \cdots > d_n\} \subset \{1, \ldots, d\}$.
A simple inductive argument shows that $\Sigma_{k+1}$ is contained in $\Sigma_k$. In particular $d^k_i$ is non-increasing as a function of $k$ and there exists therefore $k_0$ such that $d^k_i$ is constant for $k \geq k_0$. Moreover, $\nu(d^k_i,k)$ is non-increasing for $k \geq k_0$. Hence, up to eventually taking a larger $k$, $\nu(d^k_i,k)$ is also constant for $k \geq k_0$. That means that the union of the components of $\Sigma_k$ of maximal dimension is a constant set for $k \geq k_0$. In particular, its image through $A_i$ is constant for every $i$, implying that $d^k_i$ is non-increasing for $k \geq k_0$.

The same argument as above shows that, up to increasing $k$, the union of the components of $\Sigma_k$ of dimension $d^k_i$ is a constant set for $k \geq k_0$. Iterating the argument finitely many times, we get that $\Sigma_k$ is constant for $k$ large enough.

**Lemma 11**. Let $(A_1, \ldots, A_M)$ be a finite family of matrices and $M = \sum_{i=1}^{M} |d^k_i(k)k|$ be the event of all the matrices $A_i$. Let $C = \max_{i} \epsilon_i$, we denote by $V_k$ the set $\{k \geq k_0, \nu(d^k_i,k) = \nu^k_i, i \in \{1, \ldots, M\}\}$.

Notice that this notion of accessible set is different from others in appearing in the literature (see for instance [24]), where the initial point is usually fixed and the switching law is not the only controlled parameter.

**Remark 12.** Following the procedure of the proof of Lemma 11, one can explicitly find an upper bound on $k$ which depends on $n$ and $M$ only. Hence, $\Sigma_k(A_1, \ldots, A_M)$ can be computed algorithmically in finitely many steps.

From now on, given a finite system of type (1), we write $\Sigma_k(A_1, \ldots, A_M) = \cup_{i=1}^{M} V_i$ where $s \in N, s_i = T_{k}(R^s_i)$ and $T_{k} : R^s \rightarrow R^s$ is a linear injective map for $h = 1, \ldots, s$. Since, by definition, every trajectory of (1) lies inside $\Sigma_k(A_1, \ldots, A_M)$ after a finite number of steps, the existence of a Lyapunov function defined only on $\cup_{i=1}^{M} V_i$ guarantees the asymptotic stability of the system. This observation leads to the following result which introduces a relaxed version of the LMIs corresponding to (5)–(6) in the degenerate case.

**Proposition 13.** Let $(1)$ be finite. If there exist $M$ symmetric matrices $P_1, \ldots, P_M$ such that

$$T_{k}^{-1} P_{T} T_{k} > 0, \quad i = 1, \ldots, M, \quad h = 1, \ldots, s, \quad (20)$$

$$T_{k}^{-1} (A_i^T P_j A_i - P_1) T_{k} < 0, \quad i, j = 1, \ldots, M, \quad h = 1, \ldots, s, \quad (21)$$

then system (1) is uniformly asymptotically stable.

4.2. Comparison between different notions of quadratic stability in the degenerate case

In the degenerate case PTD-quadratic stability can be expressed by means of LMIs (see Theorem 14) that are in general not equivalent to those obtained in Section 3.1 for nondegenerate systems. These new LMIs are the same as those introduced in Proposition 13, except for condition (20), which is replaced by the stronger requirement that each $P_i$ is positive definite.

**Theorem 14.** Let $(1)$ be finite. Then $(1)$ is PTD-quadratically stable if and only if there exist $P_1, \ldots, P_M$ positive definite such that (21) holds true.

**Proof.** Assume first that there exist $P_1, \ldots, P_M > 0$ satisfying (21). Define $v(x, \xi) = x^T P_j x$ for $x \in R^n$ and $\xi = 1, \ldots, M$. Let $k$ be as in the statement of Lemma 11. In order to show that (1) is PTD-quadratically stable it is enough to take the Lyapunov function $(k, \xi, x) \mapsto V(k, \xi, x)$ of the form $V(k, \xi, x) = \phi(k) v(x, \xi)$ with $\phi(k) = \beta \max_{k<\infty} k_0 \beta$ large enough. Now assume that (1) is PTD-quadratically stable and fix $(k, \xi, x) \mapsto V(k, \xi, x)$ and $(k, \xi) \mapsto P_{k, \xi}$ as in Definition 5. Denote by $\Sigma_\infty$ the set $\Sigma_\infty(A_1, \ldots, A_M)$. The proof can then be concluded following exactly the same steps as in the proof of Theorem 6: Eq. (10) can be proved to hold on $\Sigma_\infty$, and the same compactness argument which is used to prove (11) implies that there exist $\alpha > 0$ and $P_1, \ldots, P_M > 0$ such that $A_i^T P_j A_i - P_j > -\alpha |x|$ on $\Sigma_\infty$ for every $i \in \{1, \ldots, M\}$, proving (21).

When $\Sigma_k$ is linear, PD-quadratic stability on $\Sigma_k$ (in the sense of Proposition 13) is equivalent to PD-quadratic stability on the entire $R^n$, as proved below. The same is not true in general, as illustrated by a counterexample at the end of this section.

**Proposition 15.** Let $(1)$ be finite. Assume that $\Sigma_k = \Sigma_k(A_1, \ldots, A_M)$ is a linear subspace of $R^n$. Assume that there exist symmetric matrices $P_1, \ldots, P_M$ satisfying (20) and (21). Then $(1)$ is PD-quadratically stable.

**Proof.** Define recursively $\Sigma_k$, for $k \in N$, in such a way that $\Sigma_0 = \Sigma_{\infty}$ and $\Sigma_k = \Sigma_{\infty} \cap \Sigma_k$ for every $k \in N$. Notice that $(A_i(\Sigma_k)) \subset \Sigma_k$ for every $i = 1, \ldots, M$. Hence, $\Sigma_k \subset \Sigma_k$. By recurrence we get $\Sigma_k \subset \Sigma_k$ for every $k \in N$. Moreover, the non-decreasing sequence of linear spaces $\Sigma_k$ reaches $R^n$ in a finite number of steps. Indeed, let $k$ be such that $\cup_{i=1}^{M} N_k = \Sigma_k$ and assume by contradiction that $\Sigma_k \neq R^n$. Hence, for every $x \in R^n \setminus \Sigma_k$, one has $x \notin (\cap \Sigma_k) \Sigma_k$ so that there exists $i \in \{1, \ldots, M\}$ such that $A_i x \notin \Sigma_k$. This means that, starting from any point $x$ outside $\Sigma_k$ there exists a sequence $\{i_j\} \subset \{1, \ldots, M\}$ such that $A_{i_j} x \notin \Sigma_k$. This contradicts the characterization of $\Sigma_k$ given in Lemma 11, which would imply that there exist $k \in N$ such that $A_{i_j} x \notin \Sigma_k \subset \Sigma_{\infty}$.

We claim that for every $k$ there exist $P_{k_1}, \ldots, P_{k_M} > 0$ such that $A_i^T P_j A_i - P_j < 0$ on $\Sigma_k$ for every $i, j \in \{1, \ldots, M\}$. The thesis of the proposition follows taking $k = k_0$.

For $k = 0$ the assertion is true because of the hypothesis of the proposition. Indeed one can set $P_{0} = P + P_i$, where the positive semidefinite symmetric matrix $P$ satisfies $P = 0$ on $\Sigma_\infty$ and $P_i > \|P\| |x|$ on the orthogonal space to $\Sigma_\infty$, denoted by $\Sigma_\infty$. Assume that the assertion is true for a given $k \geq 0$. We look for matrices $P_{k+1}, \ldots, P_{k+1}, P_{k+1} > 0$ in the form $P_{k+1} = P + P_i$, where $P_i > \|P\|$ is positive semidefinite and $P_i < 0$ on $\Sigma_\infty$. Let $\epsilon_i, R_i > 0$ be such that $A_i^T P_{k+1} A_i - P_i < -\epsilon_i |x|$ on $\Sigma_k$ and $\|A_i^T P_{k+1} A_i - P_i\| < R_i$ for every $i, j \in \{1, \ldots, M\}$. We have $x^T (A_i^T P_{k+1} A_i - P_i)x = x^T (A_i^T P_{k+1} A_i - P_i) x_k + x^T (A_i^T P_{k+1} A_i - P_i) x_2 + 2 x^T (A_i^T P_{k+1} A_i - P_i) x_3 = -\epsilon_i |x|_1^2 + R_i |x_2|_1^2 + 2 |x_3|_1 |x_2|_1 - x_3^T P_{k+1} x_2$.

Now, for $x \in k_1^k$, we considered the decomposition $x = x_1 + x_2$, with $x_1 \in \Sigma_k$ and $x_2 \in \Sigma_{k+1} \cap (\Sigma_{k+1})^\perp$. Thus, by choosing $P_i$ in such a way that $P_i > (R_i + R_i^2/\epsilon_i) |x|$ on $\Sigma_{k+1} \cap (\Sigma_{k+1})^\perp$, we get that $A_i^T P_{k+1} A_i - P_i < 0$ on $\Sigma_{k+1}$, completing the proof of the proposition. □

**Proposition 15** has the following corollary, in the spirit of Theorem 6.

**Corollary 16.** Let $(1)$ be finite and assume that $\Sigma_k = \Sigma_k(A_1, \ldots, A_M)$ is a linear subspace of $R^n$. Then $(1)$ is PD-quadratically stable if and only if there exist $M$ symmetric matrices $P_1, \ldots, P_M$ satisfying (20) and (21).
Proof. Let (1) be PTD-quadratically stable. Notice that the restriction of (1) to $S_\infty$ is a well-defined, nondegenerate, PTD-quadratically stable system. Theorem 6 then implies that it is PD-quadratically stable. By extending the quadratic forms yielding PD-quadratically stable system. Theorem 6 then implies that it is

The converse implication being trivial, the corollary is proved.

Example 17. We conclude the section by noticing that Proposition 15 cannot be extended in general to the case where $S_\infty$ is not linear. A counterexample can be constructed as follows. Take $d = 3$

$$A_{\Sigma} = \{A_1, A_2\}, \quad A_1 = \begin{pmatrix} \lambda & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad A_2 = \begin{pmatrix} -1 & 0.3 & -3 \\ 0.5 & 0 & 1.5 \\ 0 & -0.3 & 0 \end{pmatrix}.$$ 

Clearly, for $\lambda \neq 0$, $S_\infty$ is the union of the plane $\text{span}\{-2e_1 + e_2, e_1 - e_2\}$ and the line $\mathbb{R}e_1$.

It can be checked numerically (for instance by using the package yalmip for matlab) that if $\lambda \geq 0.863$ then the system is not PD-quadratically stable. On the other hand, by taking the positive definite matrices

$$P_1 = \begin{pmatrix} 10.6 & 5.4 & 1.3 \\ 5.4 & 18.3 & -0.2 \\ 1.3 & -0.2 & 20.2 \end{pmatrix}, \quad P_2 = \begin{pmatrix} 12.4 & 9.6 & 17.9 \\ 9.6 & 38.3 & -22.8 \\ 17.9 & -22.8 & 89.6 \end{pmatrix}$$

one can check that, if $|\lambda| \leq 0.868$, then (21) is satisfied with $s = 2$ and

$$T_1 = e_1, \quad T_2 = \begin{pmatrix} -2 & 1 \\ 1 & 0 \\ 0 & -1 \end{pmatrix}.$$ 

In particular if $\lambda \in [0.863, 0.868]$ then the system is PTD-quadratically stable but not PD-quadratically stable.

Consider now the polytopic system corresponding to $A_{\Sigma} = \text{conv}(A_1, A_2)$, where $A_1, A_2$ are defined as above. For every $\lambda \neq 0$ this system is nondegenerate, in the sense of Remark 7. Hence PTD-quadratic stability and PD-quadratic stability (and poly-quadratic stability) are equivalent. In particular, they fail to hold for $\lambda \in [0.863, 0.868]$. However, the uniform asymptotic stability of the system can be deduced from the first part of Proposition 4.

In general, then, the uniform asymptotic stability of a polytopic system can be tested by the LMI (20) and (21) which are less conservative than the usual inequalities (5) and (6).

Conclusion

We compared different notions of stability for discrete-time switched systems of type (1). We first proved (Section 3.1) that, if there exists $\xi \in \Sigma$ such that $A_\Sigma$ is invertible, looking for a quadratic Lyapunov function in its more general form $V(k, \xi, x) = x^T P(k, \xi) x$ (that is, in a class which depends on an infinite number of parameters) is equivalent to looking for it in the much smaller class $V(\xi, x) = x^T \left( \sum_{i=1}^{M} P_i x \right)$ (which depends on finitely many parameters). Such equivalence does not hold in general when the modes corresponding to the vertices of $\Sigma$ are degenerate. In the latter case, we proposed a relaxation of the LMI test for stability based on the notion of eventual accessible set. We also discussed the problem of detecting through quadratic Lyapunov functions the stability of polytopic switched systems whose switching functions have some common bound on the speed of variation.
